The GS1 System Architecture

Issue 2.0, 23 March 2013

7 Document Summary

Document Item	Current Value
Document Title	The GS1 System Architecture
Date Last Modified	23 March 2013
Current Document Issue	Issue 2.0
Status	Final
Document Description	This document defines and describes the GS1 System Architecture.

8 Contributors

67 1. Introduction

68 This document defines and describes the GS1 System Architecture. GS1 is an international
69 not-for-profit association with Member Organisations in over 100 countries. GS1 is
70 dedicated to the design and implementation of global standards and solutions to improve the
71 efficiency and visibility of supply and demand chains globally and across sectors. The GS1
72 System+ is the collection of standards, guidelines, solutions, and services created by the
73 GS1 community through GS1+ community development processes, and is the most widely
74 used supply chain standards system in the world.

75 The primary audience for the GS1 System Architecture includes end users, solution
76 providers, GS1 Member Organisations, and others engaged in the definition and
77 implementation of the GS1 System. For the purposes of this document, an end user is any
78 organization that employs the GS1 System as a part of its business operations. A solution
79 provider is an organization that implements for end users systems that are based upon or
80 implement the GS1 System. GS1 standards are available for use by any party.

81 This document has several aims:

82 To enumerate, at a high level, each of the hardware, software, and data standards
83 that are part of the GS1 System and to show how they are related. These standards
84 are implemented by hardware and software systems, including components
85 deployed by individual end users as well as GS1 Services deployed by GS1, its
86 delegates, and others.

87 To explain the underlying technical foundations that have guided the design of
88 individual standards and service components within the GS1 System. These
89 underlying foundations provide unity across all elements of the GS1 System and
90 provide guidance for the development of future standards and new services.

91 To provide architectural guidance to end users and solution providers seeking to
92 implement GS1 Standards and to use GS1 Services, and to set expectations as to
93 how these elements will function.

94 To define the top-level architecture of GS1 Services, which provide common services
95 to all end users, through interfaces defined as part of the GS1 System.

96 This document exists only to describe the overall architecture, showing how the different
97 components fit together to form a cohesive whole. Other documents to provide the technical
98 detail required to implement any part of the GS1 System. Specifically:

99 Individual hardware, software, and data interfaces, as well as their use in open
100 supply chain application contexts, are defined normatively by GS1 Standards, or by
101 standards produced by other standards bodies and referenced by GS1 Standards.
102 GS1 Standards are developed by the GS1 Community through the Global Standards
103 Management Process (GSMP). GS1 Standards are normative and implementations
104 of some GS1 Standards are subject to conformance and certification requirements.

105 An example of an interface (a hardware interface, in this case) is the UHF Class 1 Gen 2
106 Tag Air Interface, which specifies a radio-frequency communications protocol by which a
107 Radio Frequency Identification (RFID) tag and an RFID reader device may interact. This
108 interface is defined normatively by the UHF Class 1 Gen 2 Tag Air Interface Standard.

109 The design of hardware and software components that implement GS1 Standards
110 are proprietary to the solution providers and end users that create such components.
111 While GS1 Standards provide normative guidance as to the behaviour of interfaces
112 between components, implementers are free to innovate in the design of
113 components so long as they correctly implement the interface standards.

114 An example of a component is an RFID tag that is the product of a specific tag
115 manufacturer. This tag may comply with the UHF Class 1 Gen 2 Tag Air Interface
116 Standard; even if it does, the specific implementation embodied in the design of the chip
117 and its supporting software is not part of the GS1 System Architecture.

118 A special case of components that implement GS1 Standards are shared network
119 services that are operated and deployed by GS1 itself, by other organizations to
120 which GS1 delegates responsibility, or by other third parties. These components are
121 referred to as GS1 Network-based Services, and provide services to all end users.

122 An example of a GS1 Network Service is the GS1 Global Registry, which provides a
123 registry through which a GS1 identification key may be associated with one or more
124 Global Data Synchronization Network Data Pools. The Global Registry is logically
125 operated by GS1; from a deployment perspective this responsibility is delegated to a
126 service provider contractor of GS1 that operates the servers and database that comprise
127 the Global Registry.

128 At any moment in time, there are many parts of the GS1 System that are well established
129 and for which GS1 Standards already exist. There are other parts of the GS1 System that
130 are undergoing evolution and enhancement, to meet needs that are determined based on
131 the analysis of known use cases. In these cases, the architectural approach may not yet
132 been finalized, though architectural analysis may be underway within the GS1 Architecture
133 Group. Developing standards or designing additional network services depends on the
134 definition of a broader collection of use cases and their abstraction into general
135 requirements. This document clearly identifies which parts of the GS1 System are well-
136 established architecturally and which parts are the subject of future work. This document will
137 be the basis for working through and ultimately documenting the architectural decisions
138 around the latter parts as work continues.

139  This document is a companion document to the GS1 System Landscape document. The
140 GS1 System Landscape provides a structured, complete catalogue of all GS1 Standards,
141 including a synopsis of each. The present document complements the GS1 System
142 Landscape by providing an architectural view of how the components of the GS1 System fit
143 together and the foundations that underlie the entire system. The emphasis in the present
144 document is on elucidating these relationships, not necessarily describing each and every
145 component. Throughout this document, the reader is referred to relevant sections of the
146 GS1 System Landscape by means of the  icon as illustrated to the left of this
147 paragraph; through these references, together with the standards themselves, the interested
148 reader may find more detail.

149 2. Overview of GS1 System Architecture

150 The GS1 System provides the foundation for enhancing open supply chains through the use
151 of digital information. The open nature of supply chains shapes the general orientation of
152 GS1 Standards, placing a particular emphasis on achieving interoperability through broadly
153 accepted interface definitions. The business needs of supply chain participants determine
154 the types of interface definitions that require standardization, and in particular lead to a
155 portfolio of standards that are concerned with *identification* of real-world entities (both
156 physical and virtual), *capture* of identification and other data from physical objects, and
157 *sharing* of information concerning real-world entities among the participants in the supply
158 chain.

159 2.1. The Role of Standards

160 The GS1 System is primarily concerned with raising the efficiency of business processes
161 and providing cost savings through automation based on globally unique identification and
162 digital information. The role of GS1 Standards in this area is to further the following
163 objectives:

164 *To facilitate interoperability in open supply chains*

165 For supply chain trading partners to exchange information, they must have prior
166 agreement as to the structure and meaning of data to be exchanged and the
167 mechanisms by which exchange will be carried out. GS1 Standards include data
168 standards and information exchange standards that form the basis of cross-enterprise
169 exchange. Likewise, for trading partners to move physical objects amongst themselves,

170 they must have prior agreement as to how physical objects will carry identification that is
 171 mutually understandable and physically affixed using data carriers that are interoperable.
 172 GS1 Standards include standards for physical data carriers (i.e., bar codes and RFID
 173 tags) and data standards governing the encoding of data on those carriers.

174 *To foster the existence of a competitive marketplace for system components*

175 GS1 Standards define interfaces between system components that facilitate
 176 interoperability between components produced by different vendors or by different
 177 organizations in-house development teams. This in turn provides choice to end users,
 178 both in implementing systems that will exchange information between trading partners
 179 and in those that are used entirely internally. Moreover, the existence of standards helps
 180 to avoid fragmentation in the market for system components, which leads to economies
 181 of scale that ultimately reduce costs for end users.

182 *To encourage innovation*

183 GS1 Standards define interfaces, not implementations. Implementers are encouraged to
 184 innovate in the products and systems they create, while interface standards ensure
 185 interoperability between competing systems. By building upon a standard foundation,
 186 implementers can have greater confidence in the eventual adoption of their products and
 187 systems, and therefore the confidence to invest in innovation.

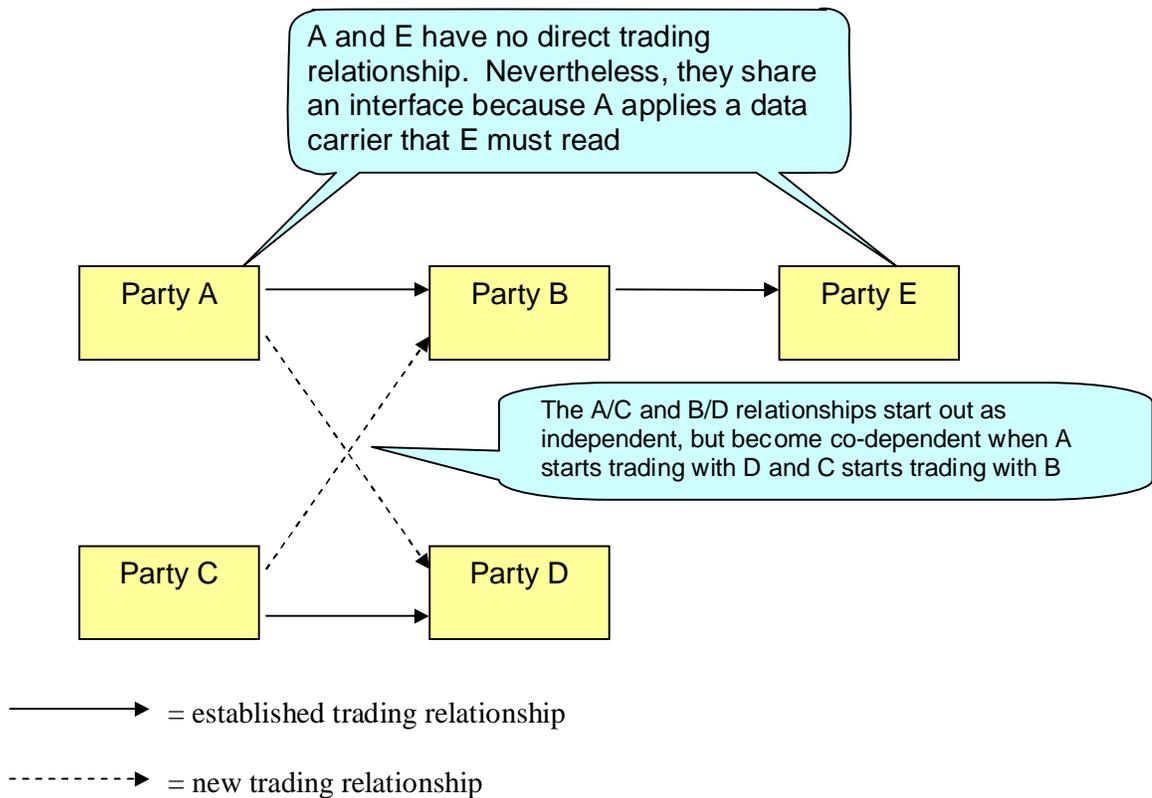

188 GS1's structure and processes enable it to engage a community of users that have an
 189 implicit consensus to use standards (at least some part of the GS1 System according to their
 190 needs) and to use them according to the published specifications. This consensus is partly
 191 achieved because all users have the opportunity to participate in the development and
 192 ongoing maintenance of the standards and mainly because there is a strong commercial
 193 incentive to be part of the standards community. Achieving the three objectives listed above
 194 depends on adoption by a substantial community of users and as the community grows the
 195 benefits to each user multiply. GS1's community of end users is at least as important as
 196 the standards themselves.

197 2.2. Open Supply Chains

198 A *supply chain* is a set of companies and other organizations involved in trading and other
 199 business relationships with one another. In many cases, supply chains are concerned with
 200 the trade of physical objects such as tangible products, parts, raw materials, and the like.
 201 Supply chains may also involve trade of non-physical objects such as music downloads,
 202 video-on-demand, telephony services, electricity, virtual world products, and so on.

203 An *open* supply chain is one in which the complete set of trading partners is not known in
 204 advance and which changes continually.¹ This has great significance for the architecture of
 205 information systems. The building blocks of an information systems architecture are the
 206 interfaces between different system components, and in a supply chain context the most
 207 important interfaces are those that exist between different companies in the supply chain.
 208 For example, in an interface for communicating digital purchase order information, one
 209 company (the buyer) is the sender of data, and another company (the seller) is the receiver.
 210 In a closed supply chain, a fixed universe of trading partners is known in advance, and so
 211 interfaces can be negotiated in a controlled, coordinated way, and change management is
 212 simplified because all parties can agree to make changes simultaneously. In an open supply
 213 chain, by contrast, the parties on either side of an interface may not even know about each
 214 other.

¹ The word *open* in *open supply chain* has a particular meaning as defined in this section. The use of the word *open* in this context should not be confused with other meanings that are also important to the GS1 System Architecture. In particular, *open standard* refers to a standard that may be freely adopted by any end user, and the word *open* is also used in security discussions to refer to a lack of or lenient access control. These are different meanings of the word *open*.

231
232
233
234
235
236
237
238
239

The open nature of supply chain interfaces manifests itself two ways, as illustrated in the above figure. Firstly, an interface may exist between two companies that do not have a direct business relationship. For example, a manufacturer may mark a product with machine-readable data in a bar code, the product is sold to retailers through distributors, and this bar code is read by all retailers who receive the product. The bar code is an interface between the manufacturer and the retailers, but the manufacturer's only business relationship is with distributors.

Secondly, as trading relationships come and go, a company may find that it needs to extend an existing interface to encompass new companies. For example, suppose that Companies A and B are in a trading relationship and utilize an electronic interface for exchanging purchase order and invoicing information. Companies C and D are in a similar relationship. Some time later, Company A may find that it needs to trade with Company D, and likewise C may find that it needs to trade with B. Company A would like to use the identical interfaces and supporting information systems to trade with C as it does to trade with B, and likewise for C as it trades with B and D.

Both of these manifestations of open supply chains have a profound influence on the design of information interfaces. They require that interface definitions be negotiated and implemented *outside* the context of any particular trading relationship, and be adhered to by all parties so that interoperability will be achieved despite the fact that the companies on each side of the interface are not able to negotiate in advance. It leads to the definition of broadly accepted industry standards, in which the emphasis is placed on interoperability, maximum applicability to a broad range of business contexts, and minimization of choices that require pre-coordination between interfacing parties. These are precisely the principles that underlie GS1 Standards.

240 2.3. GS1 Standards: Identify, Capture, Share

241 GS1 Standards support the information needs of end users interacting with each other in
242 supply chains, specifically the information required to support the business processes
243 through which supply chain participants interact. The subjects of such information are the
244 real-world entities that are part of those business processes. Real-world entities include
245 things traded between companies, such as products, parts, raw materials, packaging, and so
246 on. Other real-world entities of relevance to trading partners include the equipment and
247 material needed to carry out the business processes surrounding trade such as containers,
248 transport, machinery; entities corresponding to physical locations in which the business
249 processes are carried out; legal entities such as companies, divisions; service relationships;
250 business transactions and documents; and others. Real-world entities may exist in the
251 tangible world (such entities are generically called *physical objects* in this document), or may
252 be virtual or conceptual. Examples of physical objects include a consumer electronics
253 product, a transport container, and a manufacturing site (location entity). Examples of non-
254 physical or conceptual entities include an electronic music download, a trade item class, and
255 a legal entity.

256 GS1 Standards may be divided into the following groups according to their role in supporting
257 information needs related to real-world entities in supply chain business processes:

258 Standards which provide the means to **Identify** real-world entities so that they may
259 be the subject of electronic information that is stored and/or communicated by end
260 users. GS1 identification standards include standards that define unique
261 identification codes (called GS1 Identification Keys) which may be used by an
262 information system to refer unambiguously to a real-world entity such as a trade
263 item, logistics unit, physical location, document, service relationship, or other entity.
264 Other GS1 identification standards define supplementary data that may be used to
265 identify or describe real-world entities.²

266 Standards which provide the means to automatically **Capture** data that is carried
267 directly on physical objects, bridging the world of physical things and the world of
268 electronic information. GS1 data capture standards currently include definitions of
269 bar code and radio-frequency identification (RFID) data carriers which allow GS1
270 Identification Keys and supplementary data to be affixed directly to a physical object,
271 and standards that specify consistent interfaces to readers, printers, and other
272 hardware and software components that connect the data carriers to business
273 applications. The industry term Automatic Identification and Data Capture (AIDC) is
274 sometimes used to refer to the standards in this group, though in the GS1 System
275 Architecture a clear distinction is maintained between identification and data capture.

276 Standards which provide the means to **Share** information, both between trading
277 partners and internally, providing the foundation for electronic business transactions,
278 electronic visibility of the physical world, and other information applications. GS1
279 standards for information sharing include data standards for master data, business
280 transaction data, and physical event data, as well as communication standards for
281 sharing this data between applications and trading partners. Other information
282 sharing standards include discovery standards that help locate where relevant data
283 resides across a supply chain and trust standards that help establish the conditions
284 for sharing data with adequate security.

285 While GS1 Standards may be used in any combination in a given business application, the
286 **Identify, Capture, Share** paradigm is pervasive in situations where GS1 Standards apply,
287 and most such business applications employ GS1 Standards from all three groups.

² Ideally, GS1 Identification standards would deal exclusively with defining GS1 Identification Keys to refer to real-world entities, and all supplementary data would be defined in GS1 data sharing standards (especially those that define master data). However, there are certain situations in which supplementary data must be physically affixed to a physical item itself, so that this data is available even if information networks are not. For this reason, certain supplementary data are defined in GS1 Identification standards so that they may be affixed to physical objects and read using GS1 Capture standards.

288 For example, consider the business processes that support the retail sale of consumer
 289 goods. GS1 Standards are commonly used as follows:

290
 291  Landscape
 292 \$1, \$2

Identify Each class of trade item (informally, each distinct product) is assigned a Global Trade Item Number (GTIN) following GS1 identification standards (specifically, the GTIN section of the GS1 General Specifications, and the GTIN Allocation Rules). By adhering to GS1 Standards, all products receive a globally unique GTIN, so that any retailer is assured of having a unique way to refer to a given trade item in its information systems, regardless of which trade items it chooses to carry (in contrast to a system where each brand owner devised its own identification system), and each product brand owner need only assign a single identifier to its trade item (in contrast to a system where each retailer devised its own identification system).

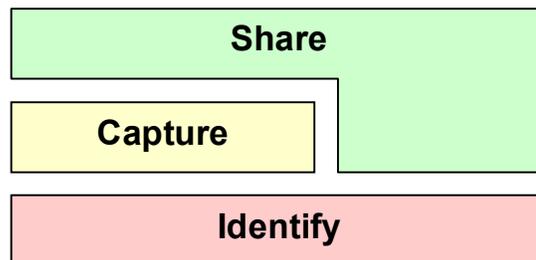

300
 301  Landscape
 302 \$3, \$4

Capture Each trade item carries its GTIN identifier directly on the product package using a bar code that adheres to GS1 bar code standards, possibly also using GS1-compliant radio-frequency identification (RFID) tags. Data capture infrastructure conforming to GS1 standards is used to automatically and reliably record trade items as they move through the supply chain, from shipping to receipt to point-of-sale.

305
 306  Landscape
 307 \$5, \$6, \$7

Share The retailer obtains from brand owners product master data conforming to GS1 master data standards; such data is used in many ways, for example to display a concise description of the product when it is scanned at the point-of-sale terminal. GS1 electronic commerce standards may be used by the retailer to reorder product from the manufacturer when supplies run low. GS1 visibility standards may be used to provide detailed information about physical events such as what products entered and exited each store, both for use by the retailer and by its suppliers (when such sharing is authorized by the retailer). Master data, electronic transaction data, and physical event data are all governed by GS1 data standards, and use the GTIN or another GS1 identification standard to refer precisely to the appropriate trade items or other real-world entities.

316 The relationship between GS1 standards for identification, capture, and sharing is depicted
 317 below.

318
 319 The key relationships are as follows:

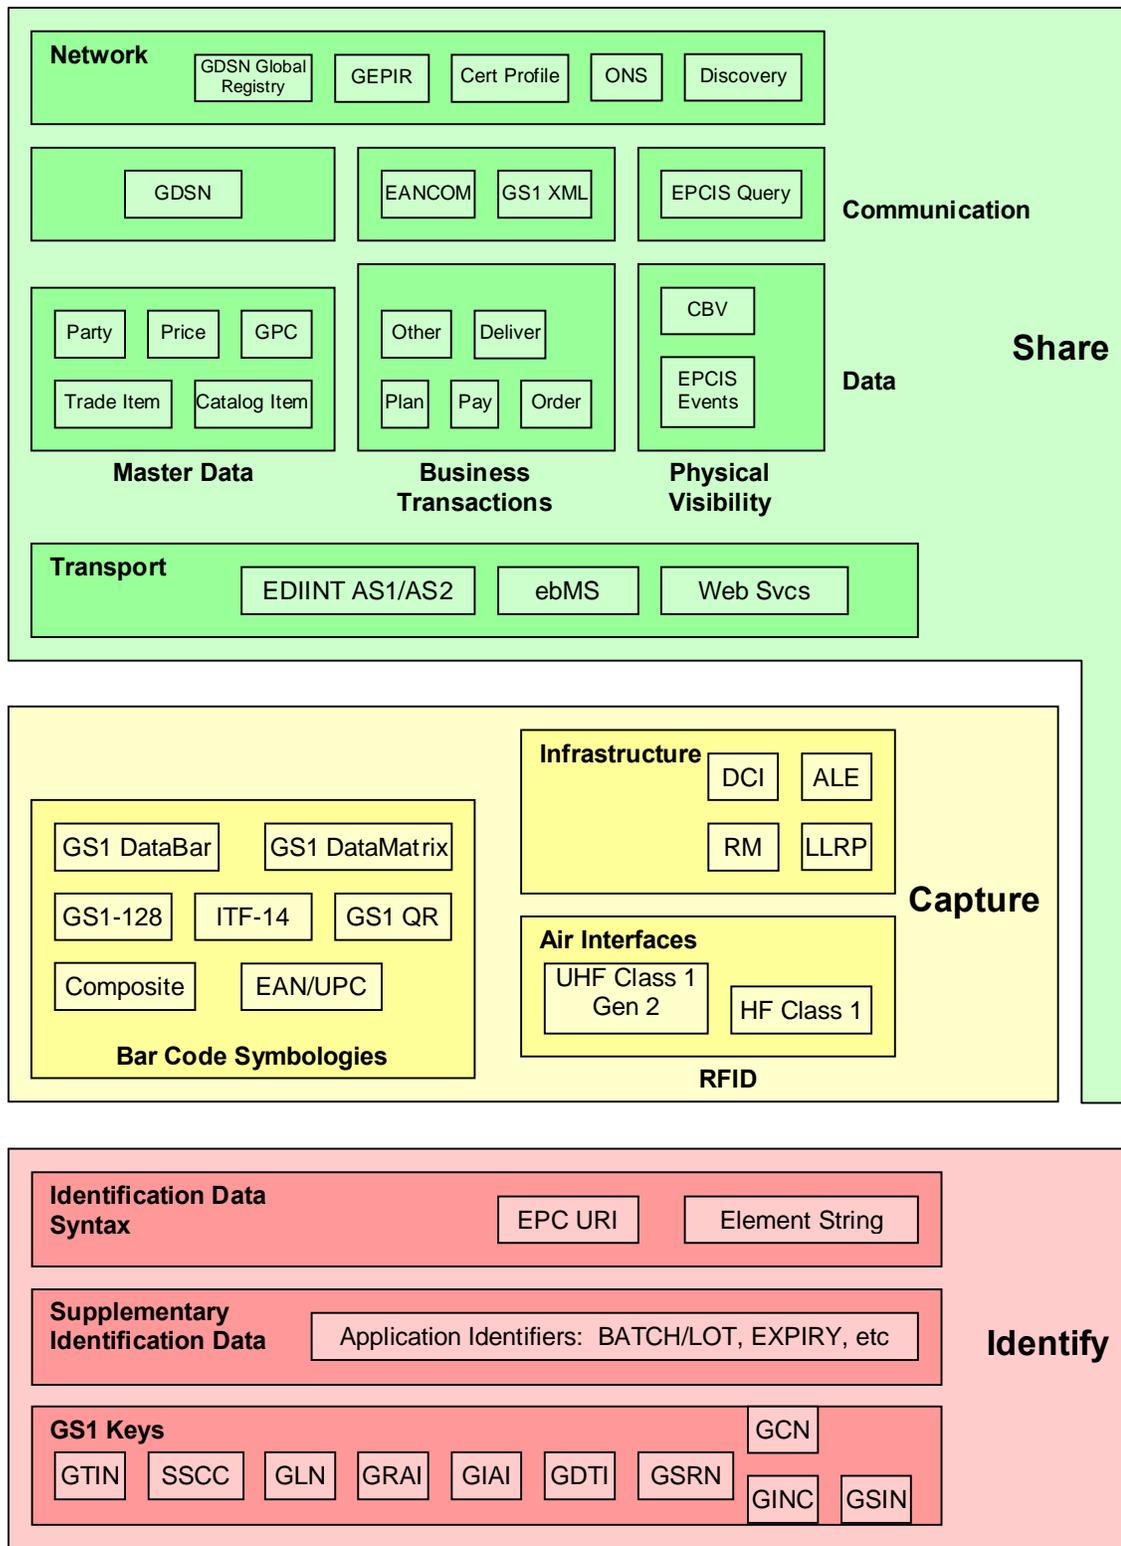

320 Both capture standards and sharing standards make use of unique identifiers for
 321 real-world entities, using GS1 identification standards. There is therefore a
 322 dependence between the capture and sharing standards and the identification
 323 standards. (Some capture and sharing standards may also be used with non-GS1
 324 identification; see Section 4.3. In such cases, the relationship of capture and sharing
 325 standards to identification still holds true, even though identification is provided by
 326 something other than GS1 standards.)

327 Where a real-world entity exists in the physical world, physical data carriers (bar
 328 codes and/or RFID tags) are used to bridge the world of the physical and the world
 329 of information (where the sharing standards exist). In such situations, GS1 capture
 330 standards come into play, and logically sit between the identification standards and
 331 the sharing standards.

332 However, there are other situations in which identification is used directly by sharing
 333 standards without any physical data capture. For example, master data describing a
 334 trade item may be shared between trading partners in advance of any instances of

335 that trade item actually being manufactured. In another example, a music download
336 is an example of something that is bought and sold as any other trade item, but the
337 entire transaction including the delivery of the product is entirely electronic and
338 therefore never involves the use of capture standards (which by definition always
339 involve a physical data carrier such as a bar code or RFID tag). For this reason,
340 GS1 sharing standards have a dependence on identification standards both directly,
341 and indirectly through the capture standards.

342 Within each broad category of standards for identification, capture, and sharing, there are
343 many individual standards that may be classified into subcategories. The following figure
344 illustrates all of the GS1 standards and how they fit into this taxonomy. They are discussed
345 at greater length in the following sections describing the identification, capture, and sharing
346 standards.

348 **2.4. GS1 Services: Assign, Register, Discover**

349 GS1 Services are facilities that are offered or coordinated by GS1 that provide benefit or
 350 assistance to other parties. Each GS1 Service is available globally, with consistent
 351 functionality as viewed by end users around the world. The responsibility for provisioning of
 352 the service and support of users is divided between the GS1 Global Office, GS1 Member
 353 Organisations, and 3rd party service providers. The details of this division of responsibility
 354 vary from service to service and are discussed below.

355 Both GS1 Member Organisations (MOs) and 3rd party service providers may also provide
 356 their own services to GS1 end users, which are not %GS1 Services+ as defined here. Such
 357 MO and 3rd party services are not necessarily offered globally and are not coordinated
 358 across GS1 as a whole. They are out of scope of this architecture document. However,
 359 local services of this kind are sometimes a proving ground for new ideas that eventually
 360 become GS1 Services.

361 **2.4.1. Functional Scope of GS1 Services**

362 Some GS1 Services are training programs and other types of customer support activities.
 363 Other GS1 Services have a more direct connection to the GS1 System Architecture, the GS1
 364 Standards, and the information systems that end users construct using GS1 Standards.
 365 These GS1 Services provide a backbone that provides identification to end users, links end
 366 users together, and enables end users and service providers to build all kinds of value-
 367 added services based on GS1 identification standards.

368 The facilities provided by the latter type of GS1 Services may be grouped into three
 369 categories, as follows:

370 *Assign* GS1 Services provide the backbone for assignment of GS1 identification
 371 keys according to GS1 Standards for identification.

372 *Register* GS1 Services provide for the registration of identification keys and
 373 associated data. Through the process of registration, the existence of a given
 374 identification key and the data associated with it can be published and made
 375 available to other organizations.

376 *Discover* GS1 Services provide for one party to discover the existence of
 377 identification keys registered by others as well as the data and services associated
 378 with those keys.

379 GS1 Services for assignment, registration, and discovery together provide a backbone that
 380 allows all the users of the GS1 System and their data to be interconnected. They support an
 381 open supply chain environment in which the population of supply chain participants is
 382 constantly changing.

383 A given GS1 Service may perform functions that span more than one of the above
 384 categories. The following table summarizes existing GS1 Services and the categories of
 385 operations they provide for different types of identification:

 Services		
Type of Identification	Assign	Register	Discover
GS1 Company Prefix	Provided by each GS1 Member Organisation	Provided by each GS1 Member Organisation	GEPIR

Services			
GS1 Identification Key	Individual assignment provided by each GS1 Member Organization (Many are self-assigned by the end user using a GS1 Company Prefix, subject to terms of use established when the GS1 Company Prefix was assigned)	GEPIR (for GTINs and GLNs that an end user chooses to register) GDSN for GTINs and GLNs ^(*) , with associated master data ONS	GEPIR (for GTINs and GLNs that are registered) GDSN for GTINs and GLNs ^(*) , with associated master data ONS
Serialized GS1 Identification Key (e.g., SGTIN)	(Self-assigned by the end user)	EPC Discovery Service (under development)	EPC Discovery Service (under development)

386
387
388
389

(*) Support in GDSN for registration and discovery of information pertaining to GLNs is not nearly as well developed as it is for GTINs. There are activities currently underway within GS1 to provide enhanced services for registration and discovery of GLNs, and these services may or may not use GDSN.

390
391
392
393
394
395
396
397

The role of GS1 Services is limited to the three areas of assign, register, and discover. There may be many other types of useful services provided to end users based on GS1 Standards, but these are provided by parties other than GS1. The role of GS1 Services is to provide the minimal backbone to make it possible for other parties to implement such services and for end users to discover such services and use them. For example, ONS allows a service provider to register an association between a GTIN or other class-level GS1 Identification Key and any Internet-based network service. Such services are then discoverable using ONS as a lookup mechanism.

398

2.4.2. Division of Responsibilities

399
400
401
402
403

The responsibility for provisioning of the service and support of users is divided between the GS1 Global Office, GS1 Member Organisations, and 3rd party service providers. The goal of this division is to promote a federated approach to services where consistent functionality is available to end users on a global basis, but where GS1 Member Organisations and 3rd party service providers can cater to local markets, customs, and business models.

404

The division of responsibilities is summarized below:

Responsibility	How Provided
Interface definition of GS1 Service	<p>A consistent interface specification of the GS1 Service is employed globally. The scope of this interface specification includes:</p> <p>The interaction between the GS1 Service and an end user client. The interface specification defines the minimum required functionality between the service provider and an end user; for some GS1 Services it is possible for the service provider to provide value-added enhancements in addition.</p> <p>If the service requires coordination among the federated service providers, the interaction between providers is also governed by the interface specification.</p> <p>In some cases, this interface specification is a GS1 Standard. In other cases, the specification is a document agreed by GS1 but not formally ratified as a standard. A GS1 Standard is always used if 3rd party service providers offer the service directly to end users (as opposed to a 3rd party acting as a subcontractor to a GS1 Member Organisation in an outsourcing relationship).</p>
Deployment and operation of systems and processes that provide the service	<p>Depending on the service, systems are provided by GS1 Member Organisations (MOs) or 3rd party service providers, or both. Where a GS1 MO does not choose to provide the service directly to its end users, the GS1 Global Office may provide the service for that geography.</p> <p>Some services involve a technical component deployed by the GS1 Global Office that coordinates the systems provided by GS1 MOs and/or 3rd party service providers.</p> <p>Example: The GEPIR service is provided by systems deployed by GS1 MOs, with the GS1 GO providing a central point of coordination to federate the local systems. The GS1 GO also provides the MO-level service for MOs that cannot or do not wish to deploy their own system.</p> <p>Example: The GDSN service is provided by GDSN certified data pools, which in many cases are run by 3rd party service providers and in some cases by GS1 MOs. The GS1 GO operates the GS1 Global Registry, which facilitates the flow of data between data pools.</p>
Customer Relationship and Pricing	<p>The relationship to individual end users and pricing of services to end users are governed by the GS1 MOs and/or 3rd party service providers that provide the service, or the GS1 GO in those cases where an MO chooses not to provide the service itself.</p>

405
406

Within the above framework, the architecture of each GS1 Service varies according to the business requirements for that service.

407 **3. General Considerations**

408
409
410
411

The term %GS1 System+refers broadly to all of the artefacts created by the GS1 community, including GS1 Standards, GS1 Guidelines, GS1 Solutions, and GS1 Services. This section defines more precisely what is meant by each of these terms and makes some general statements about how they are used.

412 **3.1. Standards, Guidelines, Solutions, Services**

413

There are four types of artefacts that make up the GS1 System:

414 **GS1 Standards** A GS1 Standard is a specification that defines the behaviour of
415 one or more system components so that certain goals are achieved. Typically these
416 goals are interoperability of system components, whether different components
417 deployed by the same supply chain party or components deployed by different
418 supply chain parties. Standards contain *normative* statements, which specify what a
419 system component must be or do in order to be in conformance to the standard; a
420 standard is written in such a way that conformance to the normative statements is a
421 sufficient condition for a system component to achieve the interoperability or other
422 goals for which the standard is designed.

423 **GS1 Guidelines** A GS1 Guideline is a document that provides information
424 considered useful in implementing one or more GS1 Standards. A GS1 Guideline
425 never provides additional normative content beyond the standards to which it refers;
426 instead, the purpose of a GS1 Guideline is to provide additional explanation and
427 suggestions for successful implementation. While conformance to a GS1 Standard
428 may be necessary to achieve an interoperability goal, use of a GS1 Guideline is
429 never required. GS1 Standards typically focus on *what*+a system component is or
430 must do, whereas GS1 Guidelines may provide additional suggestions for *how*+
431 such a component may be implemented. GS1 Guidelines may be general in nature
432 (applying to all implementations) or may be specific to a limited number of use cases
433 or industries.

434 **GS1 Service** A GS1 Service is a facility offered or coordinated by the GS1 Global
435 Office (GO) that provides benefit or assistance to other parties. For example, GEPIR
436 is a lookup service coordinated by the GS1 GO that provides all end users with the
437 ability to look up information about GS1 Identification Keys.

438 **GS1 Solution** A GS1 Solution is a set of elements from the GS1 portfolio, those
439 elements being GS1 Standards, GS1 Guidelines, GS1 Services, and other GS1
440 Solutions. In a GS1 Solution, this set of elements is brought together to address a
441 specific business need or purpose. GS1 Solutions provide a convenient package by
442 means of which GS1 Member Organizations can assist end users in implementing
443 GS1 Standards to achieve particular business goals.

444 GS1 Standards and GS1 Guidelines are created by the GS1 community via the Global
445 Standards Management Process (GSMP) facilitated by the GS1 Global Office. GS1
446 Services and GS1 Solutions are created by the GS1 Global Office with the involvement of
447 the GS1 community but outside of GSMP. Distinguishing between GSMP and non-GSMP
448 helps to ensure complete transparency and definitiveness as to when GS1 plays a facilitation
449 role versus a product creation role. Some GS1 Services or GS1 Solutions may be created
450 by a GS1 Member Organisation (MO) to meet local needs.

451 GS1 Standards may be further distinguished according to the type of normative content they
452 contain, as follows³:

453 **Technical Standards** A technical standard is one that defines a particular set of
454 behaviours for a system component. Technical standards focus on *what*+a system
455 component must be or do to be in conformance to the standard. Technical
456 standards are typically written to be as broadly applicable across business sectors
457 and geographic regions as possible. While a technical standard may illustrate
458 specific business problems to which it applies, a technical standard does not specify
459 which industries or businesses must adopt the standard. An end user may choose
460 for itself whether to deploy a component that conforms to a particular technical
461 standard.

462 Technical standards may be further distinguished as follows:

463 **Data Standard** A data standard is one that defines the syntax and semantics of
464 data. Conformance to a data standard is assessed by examining a particular

³ This is a different classification than the 'identify, capture, share' classification of Section 2.3, which is a classification along functional lines. These two classifications are different ways of looking at the same standards.

465 instance or instances of data to see whether it follows the normative statements
 466 laid out in the data standard.

467 *Interface Standard* An interface standard is one that defines an interaction
 468 between system components, often by defining the syntax and semantics of
 469 messages that are exchanged between system components. Conformance to an
 470 interface standard is assessed by examining a particular system component
 471 (often a hardware or software product) to see whether it correctly generates
 472 messages and/or responds to received messages according to the normative
 473 statements in the interface standard. Most interface standards identify two roles
 474 as the interacting *roles* of the interface and a given system component is
 475 assessed for conformance to one or the other of these roles (or sometimes
 476 both).

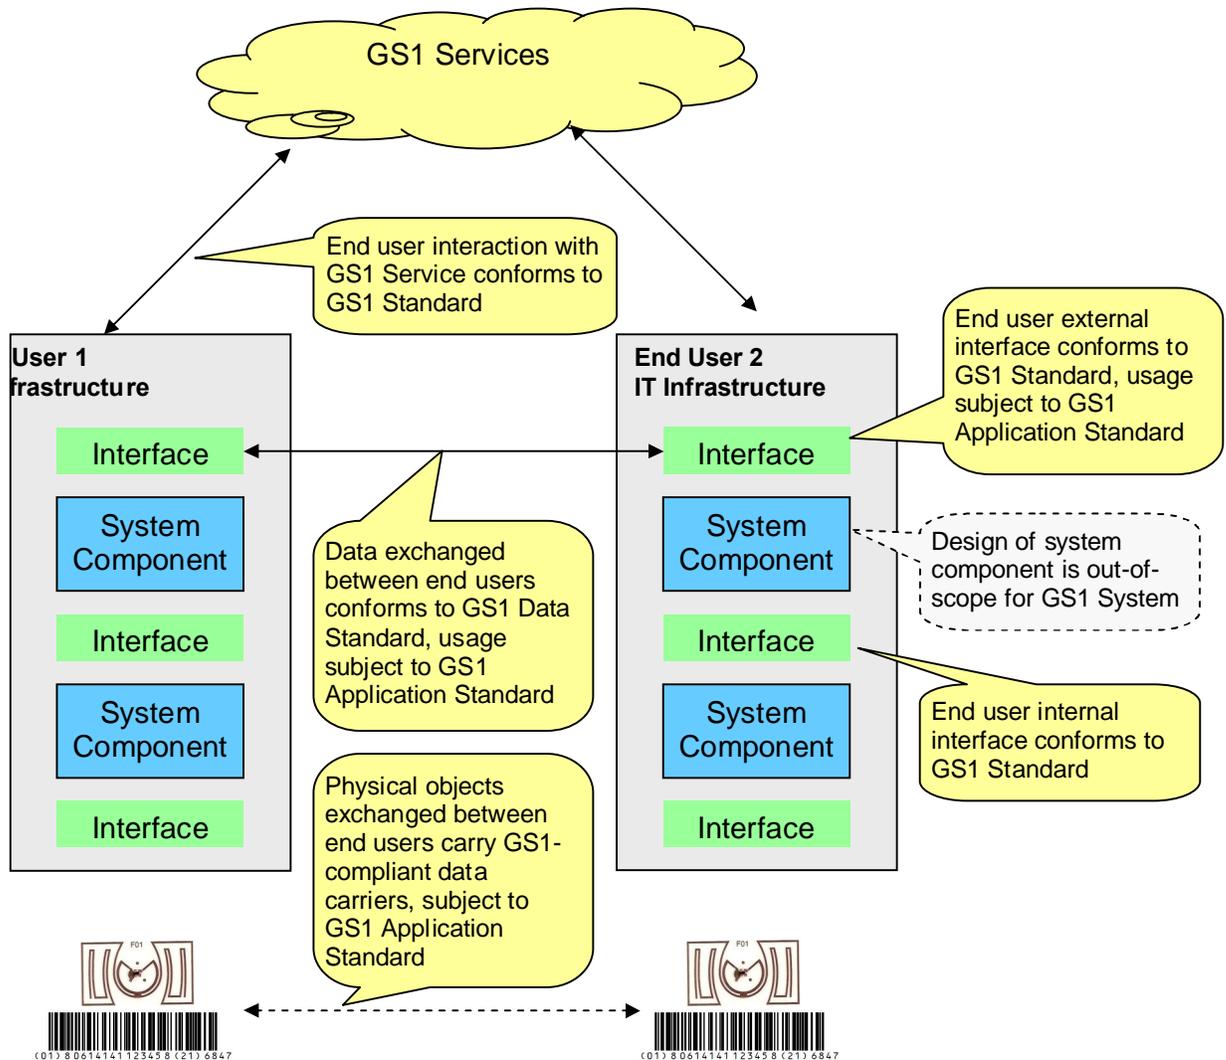

477 The distinction between data and interface standard is not always sharp, and many
 478 technical standards contain both data specifications and interface specifications.
 479 Indeed, because data is always exchanged across an interface, an interface standard
 480 nearly always contains a data standard or refers normatively to other data standards.

481 *Application Standards* An application standard is one that specifies a particular set
 482 of technical standards to which end user systems must conform in a particular
 483 business application. Application standards provide a convenient way for different
 484 end users to express their agreement to follow certain standards, in order to achieve
 485 mutually agreed interoperability goals in a given application context.

486 Application Standards are examples of *profiles*, a profile being a standard whose normative
 487 content consists exclusively of references to other standards along with normative
 488 constraints upon their use. Application standards take the form of a profile together with
 489 statements about the application area to which it applies. A profile may also be a technical
 490 standard that defines a subset of one or more other standards for a narrower purpose.

491 In general, GS1 Standards seek to specify a single way of achieving a given business goal.
 492 In some cases, GS1 Standards provide alternatives; for example, a standard that defines
 493 two different concrete syntaxes for the same abstract data construct, each optimized for a
 494 different implementation context. Having choices detracts from interoperability, and so GS1
 495 Standards offer choices of this kind only when absolutely necessary. In some cases, GS1
 496 Technical Standards offer choices and GS1 Application Standards define single choices to
 497 be used in different application contexts.

498 The following diagram illustrates how systems deployed by end users make use of GS1
 499 System artefacts.

GS1 Guidelines may assist end user in implementing a GS1 Standard

500

GS1 Solutions may suggest a combination of GS1 Standards, Guidelines, Services, and other Solutions

501

3.2. GS1 System Architecture vs. End User System Architecture

502
503
504
505
506
507
508
509

The GS1 System is a collection of interrelated standards, guidelines, services, and solutions. End users deploy systems that make use of these elements of GS1 System. In particular, each end user will have a system architecture for their deployment that includes various hardware and software components; these components may use GS1 Standards to communicate with each other and with external systems, and may also make use of GS1 Services to carry out certain tasks. A given end user's system architecture may also use alternative or additional standards, including data and interfaces beyond those governed by GS1 Standards.

510
511
512
513
514
515

The GS1 System Architecture does not define a system architecture that end users must implement, nor does it dictate particular hardware or software components an end user must deploy. The hardware and software components within any end user's system architecture may be created by the end user or obtained by the end user from solution providers, but in any case the definition of these components, apart from GS1 Services, is outside the scope of the GS1 System Architecture. GS1 Standards only define data and interfaces that the

516 end user components may implement. The GS1 System Architecture explicitly avoids
517 specification of components in order to give end users maximal freedom in designing system
518 architectures according to their own preferences and goals, while defining data and interface
519 standards to ensure that systems deployed by different end users can interoperate and that
520 end users have a wide marketplace of components available from solution providers.

521 Because the GS1 System does not define a system architecture per se, this document does
522 not normatively specify a particular arrangement of system components and their
523 interconnection. However, in order to understand the interrelationship of GS1 Standards and
524 GS1 Services, it is sometimes helpful to discuss how they are used in a typical system
525 architecture. Within this document, therefore, there are illustrations showing how
526 components of the GS1 System fit together. It is important to bear in mind, however, that
527 any such illustration differs from a true system architecture in the following ways:

528 An end user system architecture may need to employ only a subset of the GS1
529 Standards and GS1 Services depicted here. For example, two businesses may
530 agree to use GS1 eCom standards for electronic product ordering and payment, but
531 not (yet) need to use the Global Data Synchronization Network (GDSN) for master
532 data synchronization.

533 The mapping between hardware and software roles depicted here and actual
534 hardware or software components deployed by an end user may not necessarily be
535 one-to-one. For example, to carry out a business process of shipment verification
536 using EPC-encoded RFID tags, one end user may deploy a system in which there is
537 a separate RFID Reader (a hardware device), Filtering & Collection middleware
538 (software deployed on a server), and EPCIS Capturing Application (software
539 deployed on a different server). Another end user may deploy an integrated
540 verification portal device that combines into a single package all three of these roles,
541 exposing only the EPCIS Capture Interface. For this reason, this document is
542 careful to refer to roles rather than components when talking about end user system
543 elements that make use of GS1 data and interface standards.

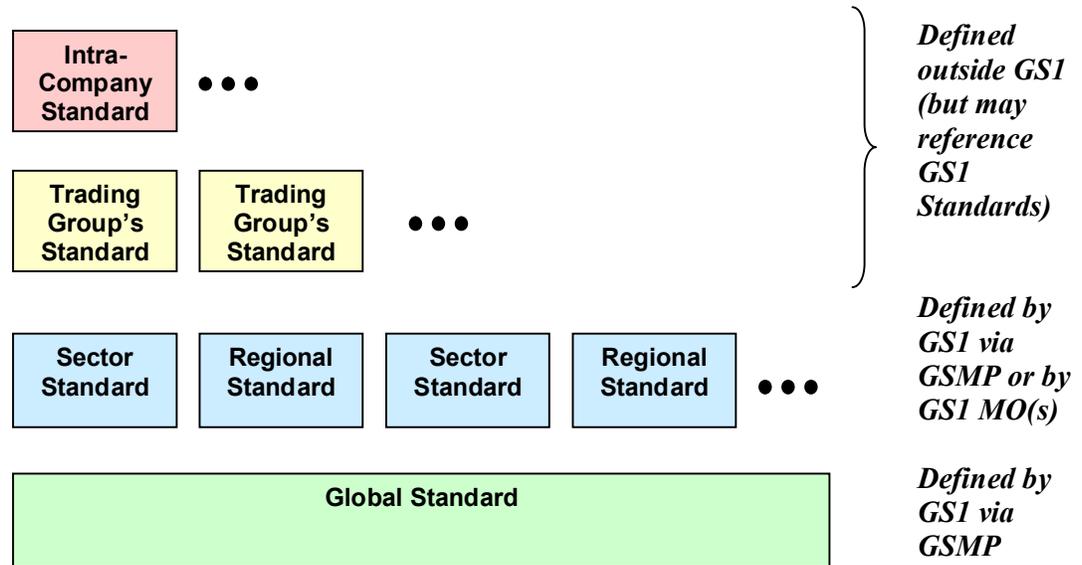

544 Moreover, roles depicted here may be carried out by end user system components
545 that may have additional responsibilities outside the scope of the GS1 System
546 Architecture. For example, it is common to have enterprise applications such as
547 Enterprise Resource Planning (ERP) systems that play the role of shipper or receiver
548 in the context of GS1 eCom standards but at the same time play many other roles
549 within the enterprise for which no GS1 Standard is relevant.

550 The overall intent of the GS1 System Architecture is to provide end users with great flexibility
551 in creating system architectures that meet their needs.

552 3.3. Scope of Standards

553 To the greatest extent possible, the components of the GS1 System are designed to be
554 broadly applicable across all industry sectors and geographical regions. However, there are
555 often needs that exist only within a particular industry but where all industry participants must
556 still rely upon normative standards in order to achieve interoperability and/or economies of
557 scale in meeting those needs. A similar pattern sometimes arises among smaller groups of
558 trading partners within an industry and even among the divisions of a single company.

559 This leads to a hierarchy of standards, illustrated below:

560

561

The hierarchy is as follows:

562

563

564

Global At the core of any implementation are the components of the GS1 System that have broad applicability across industry sectors. Most of the GS1 technical standards, including interface standards and data standards, fall into this core.

565

566

567

568

569

570

Sector / Regional A particular industry sector may profile particular technical standards for use within that industry. GS1 Application Standards are examples of such profiles. There are also certain GS1 data standards that are sector specific, such as some of the Global Data Synchronization Network (GDSN) extensions that define master data specific to product categories arising within a particular industry sector.

571

572

Regional requirements may be addressed via profiles or other normative documents created by GS1 Member Organisations to serve their respective geographical regions.

573

574

575

Both Sector and Regional standards are designed so that they can be used seamlessly with the global standards, and users who do not employ them are not disrupted by others use of them.

576

577

578

579

580

Trading Group A trading group within an industry sector or region may establish specific rules for use among themselves, building upon the GS1 System. Such rules would be developed outside of GS1, but would make reference to GS1 Standards and Guidelines. An example of a Trading Group standard is an industry consortium who specifies a particular set of GS1 global standards for use by its members.

581

582

583

584

585

Company Individual companies are encouraged to develop their own internal architectural standards to drive the consistent use of GS1 Standards across the enterprise. The publications methodology for GS1 Standards and Guidelines, including versioning and the use of permanent web locations for GS1 publications, is designed to facilitate this.

586

587

588

589

590

591

592

593

It should be noted that while a hierarchy of standards as described above can be an effective way to achieve the widest possible interoperability while still catering to narrower needs that do not rise to the global level, great care must be taken so that sector, regional, trading group, or company standards do not inadvertently create more problems than they solve. In particular, a sector, regional, or trading group standard can create problems if some companies find themselves having to operate within two or more such sectors, regions, or trading groups which have mutually incompatible requirements. Ideally, requirements are pushed to the global level whenever possible.

3.4. Consistency Across Data Standards – the Global Data Dictionary

Many GS1 Standards include normative definitions of data. These include definitions of individual data elements such as the definitions of the GS1 Identification Keys and code lists, definitions of documents comprised of many individual data elements, and definitions of messages that are exchanged between system components.

Each GS1 Standard that defines data is designed to be self-contained and so includes a normative definition of each data element; however, many data elements recur across different GS1 Standards and so some means of achieving consistency is required. The GS1 Global Data Dictionary (GDD) serves this purpose. The GDD is a compendium of the data elements defined across all GS1 Standards that are XML-based and intended for inter-company data exchange (i.e., in the Share layer). The GDD is not itself a GS1 Standard, but rather is a tool which helps to ensure consistency across all GS1 Standards in the following ways:

- It provides definitions for each distinct data element that may occur across several standards.

- When new data elements are incorporated into a new or revised GS1 Standard, the GDD helps to avoid conflicting definitions for data elements already existing and to ensure that new data elements are not given names that would be confusingly similar to existing ones.

- The working group that creates or revises an individual GS1 Standard is responsible for aligning the definitions in that standard with the GDD, with the assistance of GS1 staff dedicated to GDD maintenance.

4. Identify – GS1 Identification Keys and Supplementary Data

This section discusses the general architectural foundations that underlie GS1 Standards for identification.

4.1. Data Modelling Background

Fundamentally, GS1 Standards for identification rest on a foundation of data modelling, which is concerned with how things in the real world may be modelled in the form of data that can be manipulated by data processing systems of various kinds. This section defines some common data modelling terms that form the architectural foundation for GS1 Standards for identification discussed in the sections that follow.

4.1.1. Entities

In this section, the term *entity* is a generic term referring to that which GS1 Standards seek to identify:

Entity An entity is something in the real world that is the subject of information in an information system. An entity may be:

- Physical** A tangible object in the real world made of matter. In particular, a physical object is something to which a physical data carrier (bar code or RFID tag) may be physically affixed.

- Abstract** A virtual object or process, including legal abstractions (e.g., a party), business abstractions (e.g., a class of trade item) and so on.

637 4.1.2. Attributes

638 Information systems are concerned with associating information with entities. The items of
639 associated information are here called attributes.

640 *Attribute* A piece of information associated with an entity. An attribute may be
641 recognized if one can construct a sentence of the following form: "The [attribute
642 name] of [entity] is [attribute value]."

643 **i** Example: Example Corporation has 20 forklifts. Forklift #3 has a load capacity of 10
644 metric tons. So *load capacity* is the name of an attribute, whose value for Forklift #3
645 is 10 metric tons: "The load capacity (attribute name) of Forklift #3 (entity) is 10 metric
646 tons (attribute value)." In this example, the entity is a physical object.

647 **i** Example: Example Corporation sells a product which is a 20-count box of Example
648 Chocolate Widgets. Every box of widgets weighs 500 grams. So *weight* is the name
649 of an attribute, whose value for 20-count widgets is 500 grams: "The weight (attribute
650 name) of 20-count Example Chocolate Widgets (entity) is 500 grams (attribute value).
651 In this example, the entity is a trade item class (20-count box of Example Chocolate
652 Widgets) which is a business abstraction, not a physical object. Note that an
653 *individual* 20-count box of Example Chocolate Widgets is a physical object, but the
654 class of all 20-count boxes of Example Chocolate Widgets is a business abstraction.

655 Attributes can be classified based on how frequently they change.

656 *Static Attribute* An attribute whose value does not change over the life of the entity.
657 E.g., the load capacity of a specific forklift.

658 *Quasi-static Attribute* An attribute whose value changes infrequently over the life of
659 the entity. E.g., the last name of a person (which may change infrequently due to
660 marriage or other reasons).

661 *Dynamic Attribute* An attribute whose value changes frequently over the life of the
662 entity. E.g., the price of a product or of a stock.

663 This classification does not affect the nature of an attribute from a data modelling
664 perspective but may have a great influence on implementation choices for information
665 systems that use the attribute.

666 The above classification of attributes is related to the notion of master data, a topic that is
667 taken up in greater detail in Section 6. The term master data typically refers to attributes
668 where (a) the attribute is static or quasi-static; (b) the entity is long-lived and/or new entities
669 are not created very frequently; and (c) the attribute is of interest to many parties. Those
670 characteristics lead to certain styles of sharing of master data that would be infeasible or
671 inappropriate for other types of attributes.

672 4.1.3. Keys

673 Information systems refer to a specific entity by means of a key.

674 *Key* An attribute (or group of attributes, see below) of an entity that serves to
675 uniquely identify that entity, within some specified domain of entities. An information
676 system uses a key as a proxy for the entity itself.

677 Often a single attribute is usable as a key, but sometimes a group of attributes is required.
678 In data modelling terminology these are called simple keys and compound keys,
679 respectively.

680 *Simple Key* A single attribute that serves as a key. (E.g., in the domain of Example
681 Corporation employees, the Employee ID may be the key that identifies an
682 employee.)

683 *Compound Key* Two or more attributes which together serve as a key, where no
684 subset of those attributes taken by themselves would do so. (E.g., in the domain of

685 US cities, the combination of the %city name+and %state+attribute uniquely identifies
 686 a city, and so these two attributes together may be used as a compound key to
 687 identify a city. %City name+by itself is not a key, because Springfield, Illinois and
 688 Springfield, Massachusetts both have the same city name.)

689 In order to be usable as a key, an attribute (or set of attributes, for a compound key) must
 690 have certain properties:

691 *Uniqueness* A given key value corresponds to one and only one entity within the
 692 specified domain; two different entities within the specified domain have different
 693 values of their keys

694 *Completeness* There exists a key value for every entity within the specified
 695 domain. (i.e., the key value cannot be null)

696 *Persistence* The same key value denotes a given entity throughout the entity's life.
 697 (This implies a key is always a static attribute.)

698 It is critically important to note that the properties above depend on the application context.
 699 Therefore, whether a given attribute of an entity is usable as a key depends on the
 700 application context.

701 **i** Example: In an application run by a US State government that tracks population of
 702 cities within that State, the %city name+attribute of a city has all the properties above
 703 and is usable as a key. But in an application run by the US Federal government that
 704 tracks population of cities in all States, %city name+is not unique and therefore may not
 705 be used as a key (at least not by itself).

706 **i** Example: In the fictional country of Examplestan, citizens are assigned a taxpayer ID
 707 number for life, but those numbers may be reassigned 20 years after a person's
 708 death. In an application that only processes 10 years worth of data about
 709 Examplestan citizens, the taxpayer ID number may be used as a key, but in an
 710 application that processes 30 years worth of data the taxpayer ID may not be useable
 711 as a key.

712 The above description defines the word %key+ in the data modelling sense. %GS1
 713 Identification Keys,+discussed in greater detail in Sections 4.2 through 4.4, are a particular
 714 application of this concept. GS1 Identification Keys are defined by GS1 Standards that are
 715 intended to have very broad applicability. The goal of the GS1 General Specifications and
 716 key allocation rule standards is to define GS1 Identification Keys so that they can be used as
 717 a key in the above sense, and moreover to define them in such a way that they are likely to
 718 be usable as keys in the widest possible set of application contexts; that is, for any
 719 application context in which a GS1 Identification Key might be used, the definitions provided
 720 by the GS1 General Specifications and key allocation rule standards will likely be sufficient
 721 for the GS1 Identification Key to have the properties of Uniqueness, Completeness, and
 722 Persistence within that application context.

723 **4.1.4. Terms Relating to Construction of Keys**

724 In many of the illustrations above, a key is an attribute that an entity %already has+; that is, it
 725 has already been associated with the entity in the real world, and it can be used as a key if it
 726 can be shown to satisfy the properties above. (E.g., the city name examples above.)

727 In many applications, and in the case of GS1 Identification Keys in particular, a key is
 728 invented specifically for the purpose of being a key. Such keys are artificial constructions
 729 that would not exist as attributes of the entities involved if there were no information systems
 730 that were trying to model those entities. In this case, there is freedom to design the keys to
 731 meet information system requirements and so some design considerations apply.

732 *Syntax* An artificial key typically has syntax rules that define the universe of strings
 733 from which key values may be drawn. Common syntax rules include a choice of

734 character set, limits on length, specifying fixed or variable length, having a grammar
 735 that supports a hierarchical structure, etc.

736 **Capacity** The uniqueness and completeness requirements for being a key are
 737 affected by the capacity that is implied by the syntax rules. E.g., if the syntax rules
 738 for a key that is intended to identify an employee specify that the key is a 6-digit
 739 decimal number, but there are more than 1,000,000 employees, then it is impossible
 740 to achieve both uniqueness and completeness, and hence the 6-digit decimal
 741 number is unusable as a key.

742 **Assignment methodology** Keys can be assigned centrally, out of one single
 743 coordinating body, or in a distributed manner. The latter is a method for assigning
 744 new keys that delegates the assignment process to multiple points of control, while
 745 still achieving uniqueness. This requires strict compliance to rules of construction by
 746 all parties involved. Typically this involves a hierarchical structure where some
 747 portion of the key is assigned by a central party, and the assignment of the
 748 remainder is delegated to other parties, who may in turn delegate a portion of their
 749 portion, etc. This is the way GS1 has organised the assignment of GS1 Identification
 750 Keys, in a three level hierarchy: GS1 Global Office, GS1 Member Organization, GS1
 751 Subscriber (who assigns the final key). The hierarchical assignment process may or
 752 may not be evident in the final key. In the GS1 System this is usually evident (when
 753 a %GS1 Company Prefix+ is assigned) but not always (e.g. when individual keys are
 754 assigned directly by a GS1 Member Organization).

755 **Routability** Given the value of a key, the ability to locate data related to a key, or at
 756 least to determine an entry point to locate such data.

757 **Non-significance** The extent to which the value of the key conveys no useful
 758 information apart from uniquely identifying a specific entity within the specified
 759 domain. More precisely, a key is non-significant to the extent that it does not embed
 760 business information about the entity it identifies; such information is instead
 761 *associated* with the key. On the other hand, a key may embed information about the
 762 key itself, such as which organization is responsible for issuing the key or how to
 763 route information requests regarding the key, and still be non-significant. In general,
 764 significance severely limits the capacity of the key space (or else requires a very
 765 long key). More importantly, significance leads to severe problems if the nature or
 766 structure of the embedded information ever needs to change. For this reason, GS1
 767 keys are defined in a way that is non-significant, though as noted above the
 768 assignment process is evident in the final key.

769 **4.1.5. Terms Relating to Use of Keys in Applications**

770 Within an information system, a key is used as a proxy for the real world entity that it
 771 uniquely identifies.

772 In a particular application context, an entity may have more than one attribute (or more than
 773 one compound attribute) that is usable as a key. In this case, the application chooses one
 774 particular attribute (or compound) to use consistently as the key. This is termed the primary
 775 key.

776 **Primary key** A simple or compound attribute that is used consistently by an
 777 application as the key to refer to an entity within a specified domain.

778 Because the GS1 General Specifications do not define any particular application context, the
 779 term primary key does not arise there. An individual application may choose to use a GS1
 780 Identification Key as the primary key if appropriate.

781 An entity typically has many attributes. Some attributes have values that are simple scalar
 782 values, such as numbers or character strings. Other attributes have values that are other
 783 entities. For example, in an employee database, an employee may have an attribute
 784 %department+ that says in which department he works. But in this same database, a
 785 department may itself be an entity with attributes, and each department has an attribute
 786 %department number+ that is the primary key for the department. In this case, the value of

787 the employee's department attribute is a key for a department entity. An attribute of this
 788 kind, whose value is itself a key, is called a foreign key.

789 *Foreign key (key-valued attribute)* A simple or compound attribute of an entity
 790 whose value is conceptually another entity (the referenced entity) and in the
 791 information system is the key value for that referenced entity. If the referenced
 792 entity's key is a compound key consisting of N attributes, then the foreign key will
 793 also consist of N attributes.

794 The phrase key-valued attribute better conveys what a foreign key is, though the term
 795 foreign key is widely used and understood.

796 **4.2. GS1 Identification Keys and Supplementary Data**

797 In light of the definitions given in Section 4.1, the goal of GS1 Standards for identification can
 798 be understood as defining standardized attributes for real-world entities including, most
 799 significantly, standardized attributes that may be used as keys to refer to specific entities.

800 *GS1 Identification Key* An identifier defined by GS1 Standards that is usable as
 801 and intended as a key to refer to a specific business entity.

802 *Supplementary Data* Attributes of entities, other than primary keys, defined by GS1
 803 Standards, that may be directly affixed to an entity using a GS1 data carrier. (In
 804 some places within the GS1 General Specifications, these are simply called
 805 attributes.)

806 The above terms refer to data defined in GS1 Standards for identification. Other data is
 807 defined in other GS1 Standards.

808 GS1 Identification Keys and Supplementary Data are identified using *application identifiers*
 809 (AIs). An AI is a short string (2, 3, or 4 characters) which identifies the data element, whose
 810 brevity is particularly suited to identifying data elements when encoded into GS1 physical
 811 data carriers.

812 The following table summarizes the GS1 Identification Keys in relation to the definitions in
 813 Section 4.1. Not every key in the data modelling sense is defined as a GS1 Identification
 814 Key in the GS1 General Specifications. The candidate key column in the table below
 815 indicates what combination of GS1 Identification Keys and other data elements may serve as
 816 a key in the data modelling sense for the entity given in the first column.

Entity	Physical / Abstract	Candidate Key
Trade Item Class	Abstract	GTIN
Trade Item Lot	Abstract	GTIN + AI 10 (compound)
Trade Item Instance	Physical	GTIN + AI 21 (compound)
Logistics Unit	Physical	SSCC
Party	Abstract	GLN
Physical Location	Physical	GLN GLN + AI 254 (compound)
Returnable Asset Class	Abstract	GRAI without optional serial number
Returnable Asset Instance	Physical	GRAI with serial number
Individual Asset	Physical	GIAI
Document Type	Abstract	GDTI without optional serial number

Entity	Physical / Abstract	Candidate Key
Document Instance	Physical or Abstract	GDTI with serial number
Service Relation	Physical or Abstract (Note 1)	GSRN
Consignment	Abstract	GINC
Shipment	Abstract	GSIN
Payment Slip	Physical or Abstract	GLN + AI 8020
Coupon	Physical or Abstract	GCN without optional serial number
Coupon Instance	Physical or Abstract	GCN with serial number

817

Notes:

818

1. GSRNs are commonly used to identify recipients and providers of services in the context of a specific service relationship, and these recipients and providers are often individual people and therefore physical entities.

819

820

821

4.3. Classes of GS1 Identification Keys

822

The GS1 Identification Keys are the foundation of the GS1 System. However, some GS1 Standards make provision for the use of other systems of identification for which some organization other than GS1 is the issuing authority. For this reason a classification of keys, drawn from a GS1 perspective, is helpful in understanding the relationship between a key and the rest of the GS1 System.

823

824

825

826

827

The following classification of keys is used:

828

Class 1: Keys administered by GS1 and fully under its control

829

Class 2: Keys whose framework is controlled by GS1 by means of portion of the GS1 numbering capacity that is allocated for an identification scheme administered by an external agency

830

831

832

Class 3: Keys fully administered and controlled outside GS1 but which are supported in some part or parts of the GS1 System

833

834

Class 4: Keys that are entirely outside the GS1 System i.e. all identifiers that meet the technical definition of *key* in Section 4.1.3, but are not in the first three classes.

835

836

This classification is described in more detail below.

837

4.3.1. Class 1 Keys

838

A Class 1 key has its structure and its allocation and lifecycle rules defined by GS1. Class 1 keys always start with a GS1 Prefix⁴. They usually start with a GS1 Company Prefix licensed by a GS1 Member Organisation (MO) or by the GS1 Global Office to a user company. In some cases, they are licensed one by one by MOs to user companies. They are subject to allocation rules defined in GS1 Standards, and their association with attributes is governed by validation rules also defined in GS1 Standards.

839

840

841

842

843

844

The allocation and lifecycle rules and the standardised structure guarantee full interoperability between users of all layers of the GS1 System. This means that when a

845

⁴ This is not quite literally true, because the syntax of the GTIN-14 and SSCC keys include an extra digit that precedes the GS1 Prefix. However, from the standpoint of the allocation process, the GS1 Prefix are the first digits to be chosen during the construction of a key, so in this sense the GTIN and SSCC also start with a GS1 Prefix. Note that in the EPC syntax, the first digits *are* always the GS1 Prefix.

846 company uses Class 1 keys for its intended purpose it can be confident that its GS1
 847 compliant trading partners will be able to accept and process them per GS1 Standards.

848 Currently the Class 1 keys are GTIN, SSCC, GLN, GRAI, GIAI, GSRN, GDTI, GSIN, GINC,
 849 and GCN.

850 **4.3.2. Class 2 Keys**

851 A Class 2 key starts with a GS1 Prefix, incorporates a key administered by an external
 852 organisation, and where its corresponding Class 1 key format has a check digit it must be
 853 used and calculated in the same way as for Class 1 keys. Class 2 keys are unique with
 854 respect to Class 1 keys of the same type, and their values are a subset of all possible values
 855 of the corresponding GS1 key. Their allocation and lifecycle rules, however, are defined by
 856 an organisation external to GS1. The degree to which these rules are compatible with those
 857 of the corresponding Class 1 keys is specific to each Class 2 key. In some cases they can
 858 easily be used alongside Class 1 keys, but sometimes legal restrictions or dominant
 859 business practices lead to acceptance of Class 2 keys whose rules vary significantly from
 860 their Class 1 equivalents.

861 It is important to understand that technical compatibility is not the same in practice as
 862 interoperability. Technical compatibility is achieved by having uniqueness of values within
 863 the namespace and a similar basic structure for the identifier (e.g., GS1 Prefix and check
 864 digit). It is still possible for business or legal restrictions to be imposed requiring use of a
 865 certain format or range of values, even if such restrictions are not technically justified. It
 866 might be argued that Class 2 keys are more susceptible to these geopolitical constraints
 867 than keys in Class 1.

868 Interoperability is the ability to use the key within the context of business processes
 869 supported by GS1 standards. However, the degree of interoperability with GS1 System
 870 depends on the extent to which a Class 2 key conforms to Class 1 key functionality and
 871 rules.

872 Class 2 keys are always based on a GS1 Prefix issued by GS1 and might be based on a
 873 GS1 company prefix allocated by a GS1 Member Organisation or the GS1 Global Office.
 874 Examples include:

875 ISBNs may be used with GS1 prefixes 978 and 979 to form GTIN-13s.

876 GS1 prefix 34 is used with Club Inter Pharmaceutique (CIP) codes for
 877 pharmaceuticals in France to accommodate national numbers inside the GTIN
 878 number range

879 The Produce Electronic Identification Board uses the GS1 Company Prefix 033383
 880 combined with a commodity code issued by the Produce Manufacturers Association
 881 to create $\%EIB$ UPCs+inside the GTIN number range.

882 There must be a contractual agreement between the GS1 Global Office or a GS1 Member
 883 Organisation and the agency that administers the embedded key. This agreement specifies
 884 at minimum the following:

885 GS1 System components that can be used with the key, e.g. ISBN can only be used
 886 with the EAN/UPC data carrier

887 Restrictions that may apply, e.g. ISBN can only be used for books

888 Financial considerations

889 GS1 keys allocation and lifecycle rules

890 Validation rules

891 Compatibility with class 1 key function and syntax for example:

892 Will this class 2 key work with physical data carriers and GDSN validation rules

893 Will this class 2 key support ONS

894 Etcō

895 Restrictions on reciprocity (e.g. national or currency zones)

896 **4.3.3. Class 3 Keys**

897  A Class 3 key has its structure and its rules for use defined, administered and managed by
 898 an agency external to GS1. However this agency enters into an agreement with GS1 that
 899 enables its keys to be used in selected GS1 Standards; for example, within an EPC header.

900 It is intended that Class 3 keys are used in selected GS1 standards without disrupting users
 901 of Class 1 and Class 2 keys, but:

902 GS1 gives no assurance that Class 3 keys will be recognised by users of Class 1
 903 and Class 2 keys

904 GS1 has no expectation that systems relying upon Class 3 keys should recognise
 905 keys from Class 1 or Class 2

906 Has no expectation that systems relying upon one type of Class 3 key should
 907 recognise other types of Class 3 key.

908 Companies can take advantage of GS1 technology, network and communications standards
 909 for Class 1, 2 and 3 keys, but should not expect full interoperability between keys in
 910 Classes 1 and 2 and keys in Class 3.

911 Keys in Class 3 at the present time are the Auto-ID Center General Identifier (GID), and keys
 912 compliant with US Department of Defence (USDOD) and Airline Transport Association (ATA)
 913 standards that are based on CAGE and DoDAAC company identification. Such keys are
 914 supported in the GS1 EPC Tag Data Standard and consequently have an EPC URI that can
 915 be used in EPCIS.

916 **4.3.4. Class 4 Keys**

917 A Class 4 key is administered and managed externally to GS1 and is not accommodated by
 918 any GS1 standard. Examples include DUNS, VIN, HIBC, BIC, DOI and many others.

919 **4.3.5. Summary**

920 The following table summarises the key classification discussed above.

Class	Managed	Contract	GS1 Prefix	Interoperability*
1	By GS1	N/A	Yes	Full
2	Externally	Required	Yes	Variable
3	Externally	Required	No**	Limited
4	Externally	No	No	None

921 * Interoperability is the ability to use the key within the context of business processes
 922 supported by GS1 standards.

923 ** One exception is GID GS1 Prefix 951. While the key itself does not contain a GS1 Prefix,
 924 the portion of the key that semantically corresponds to the GS1 Prefix is 951, and this GS1
 925 Prefix is reserved for that use to avoid confusion with Class 1 and 2 keys.

926 **4.4. Identifier Syntax: “Plain”, GS1 Element String, EPC**

927  When a GS1 Identification Key or other identifier is used in an information system, it is
 928 necessarily represented using a specific concrete syntax. The syntax that is used may
 929 depend on the medium in which the identifier exists; for example, an XML message is text-

930 oriented, while the memory of an RFID tag is binary-oriented. The syntax may also depend
 931 on the context in which the identifier appears. Specifically, there are some contexts in which
 932 only one type of identifier is expected and others where more than one type of identifier may
 933 appear. In the latter case, the identifier syntax requires some means to distinguish between
 934 different identifier types.

935 GS1 Standards provide three different syntaxes for identifiers that support progressively
 936 broader application contexts:

937 *“Plain”* This syntax is just the GS1 Identification Key with no additional characters
 938 or syntactic features. For example, a Global Location Number (GLN) is represented
 939 as a 13-character string, each character being a digit. The *plain+* syntax is usable in
 940 a context where only a single type of key is expected. Examples of such single-key
 941 contexts include: a bar code symbology that is defined to only hold one type of key
 942 (e.g., ITF-14 which can only hold a GTIN), an XML element in a business document
 943 that is defined to hold only a single key (e.g., the rental record example below), a
 944 column in a database table that is intended to hold only a single key.

945 *GS1 Element String* This syntax consists of a short (2-4 character) *application*
 946 *identifier+* that indicates what type of GS1 Identification Key follows, followed by the
 947 key itself. This allows one type of GS1 Identification Key to be distinguished from
 948 another. Related to the GS1 Element String is the *concatenated element string+*, in
 949 which two or more AI-value pairs are concatenated into a single string (with
 950 delimiters, if needed). This provides a syntax for compound keys such as GTIN +
 951 Serial Number. (It also allows for concatenation of two or more keys or
 952 supplementary data elements, but then the resulting string is not itself an identifier.)
 953 The *GS1 Element String+* syntax is usable in a context where any GS1 Identification
 954 Key (Class 1 or Class 2 per Section 4.3) is expected.

955 *Electronic Product Code (EPC) URI* This syntax is an Internet Uniform Resource
 956 Identifier (URI), specifically a Uniform Resource Name (URN) beginning with
 957 *urn:epc:id:...* and the remainder having a syntax defined by the GS1 EPC Tag
 958 Data Standard. This provides a syntax for any key that identifies a specific physical
 959 object, including some Class 3 keys as defined in Section 4.3. Because of the use of
 960 URI syntax, the EPC URI is usable in a context where any Internet resource is
 961 expected, not just an identification key.

962 While any given GS1 Identification Key may be represented in more than one of the above
 963 three syntaxes, its *meaning* is always the same regardless of syntax.

964 The following table illustrates a GS1 Global Returnable Asset Identifier (GRAI) in each of the
 965 three syntaxes:

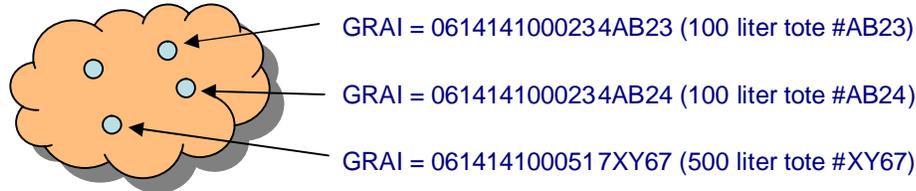

Syntax	Example	Remarks
<i>plain+</i>	0614141234561789	A GRAI composed from GS1 Company Prefix 0614141, Asset Type 123456, Check Digit 1, and Serial 789
GS1 Element String	800300614141234561789	The Application Identifier 8003 indicates the following key is a GRAI. The GS1 Element String for GRAI also includes an extra <i>+</i> padding digit immediately following the Application Identifier. The remainder of the element string is the same as the plain syntax.
EPC URI	urn:epc:id:grai:0614141.23456.789	The <i>urn:epc:id:grai:+</i> header specifies that this EPC URI corresponds to a GRAI. The GS1 Company Prefix, Asset Type, and Serial are separated by dot (<i>.</i>) characters. The check digit is not included in this syntax.

966
967
968
969

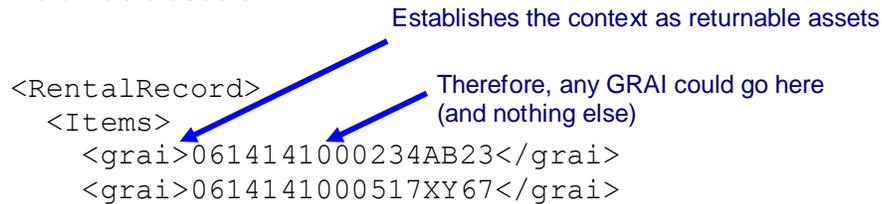

An identifier may occur in an electronic record or file, in a database, in an electronic message, or any other data context. In any given context, the producer and consumer must agree on types of identifiers that may occur, and the syntax to be used. The choice of syntax will be constrained by how narrow or broad the context is.

970
971
972
973
974
975

For example, the Global Returnable Asset Identifier (GRAI) is a key that is used to identify returnable assets, such as plastic totes and pallet skids. The set of GRAIs can be thought of as identifiers for the members of the set of all returnable assets. The plain syntax for GRAI code may be used in a context where only returnable assets are expected; e.g., in a rental agreement from a moving services company that rents returnable plastic crates to customers to pack during a move. This is illustrated below.

**GRAIs: All
returnable assets**

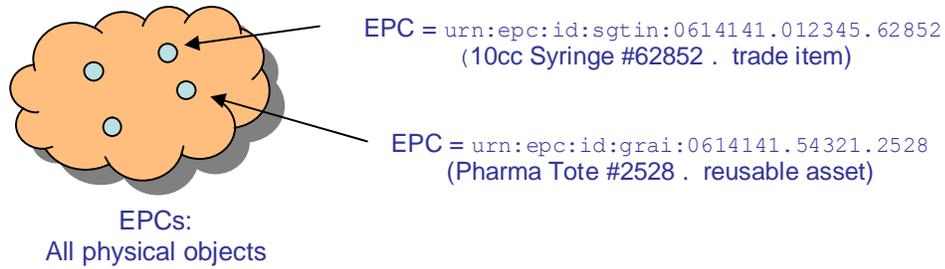

976
977
978
979
980
981

The upper part of the figure illustrates the set of all returnable assets identified by GRAIs. The lower part of the figure shows how the plain syntax for GRAI might be used in the context of a rental agreement, where only a GRAI is expected. (There is no GS1 Standard that defines a rental agreement business document, so this illustrates how end users can create their own business documents using GS1 Identification Keys.)

982
983
984
985
986

In contrast, the EPC URI provides a syntax for any identifier that names a specific physical object. The set of EPCs can be thought of as identifiers for the members of the set of all physical objects. EPCs are used in contexts where any type of physical object may appear; for example, in the set of observations arising in a hospital storage room where returnable totes, trade items, and other objects might be observed. This is illustrated below:

```

<EPCISDocument>
  <ObjectEvent>
    <epcList>
      <epc>urn:epc:id:sgtin:0614141.012345.62852</epc>
      <epc>urn:epc:id:grai:0614141.54321.2528</epc>
    
```

Establishes the context as all physical objects

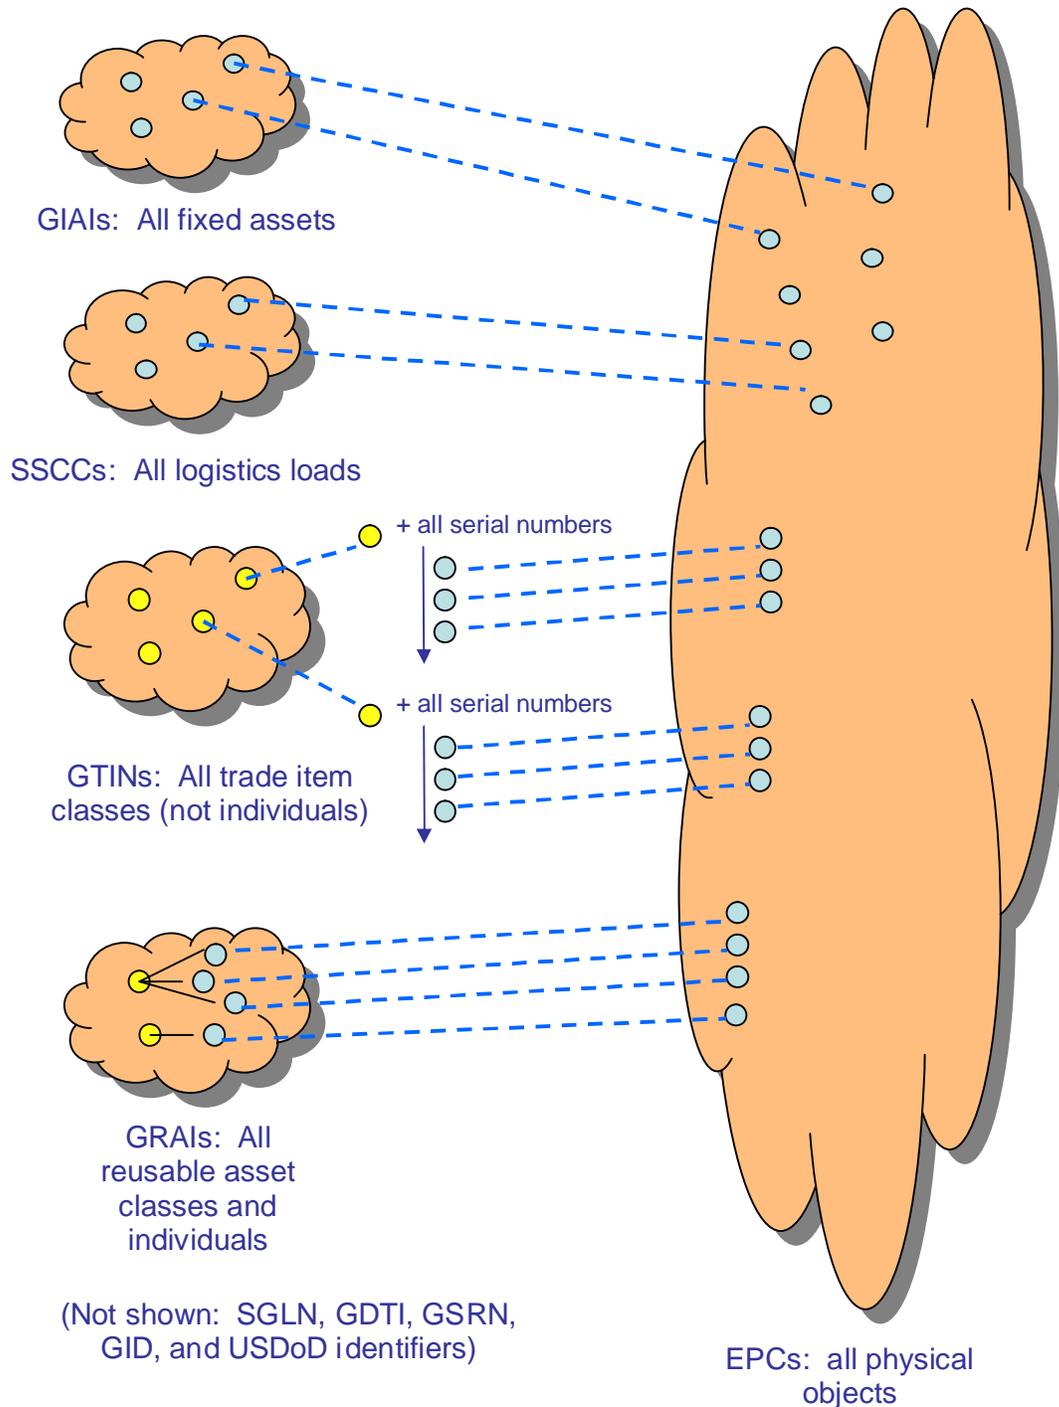

Therefore, any EPC could go here

991
992
993
994
995
996
997
998
999
1000

The upper part of the figure illustrates the set of all physical objects identified by EPCs. The lower part of the figure shows how the both a GRAI identifying a returnable asset and a serialized GTIN identifying a trade item might occur in the same business document that records a physical observation. (In this example, the business document illustrated also happens to be a GS1 Standard, namely the EPCIS standard for visibility events.)

The EPC URI can be thought of as federating different identifier types into a single syntax. For this reason, it is sometimes referred to as a *meta-key*. The correspondence between EPC URI syntax and *plain*+or GS1 Element String syntax is formally defined by conversion rules specified in Section 7 of the EPC Tag Data Standard.⁵ The well-defined correspondence between the various syntaxes allows for seamless migration of data between *plain*+ GS1 Element String, and EPC URI syntax as necessary. URI syntax also serves to embed GS1 identification into the larger universe of Internet Uniform Resource Identifiers.

⁵ Despite the title of the standard, this particular section of the EPC Tag Data Standard does not have anything to do with RFID Tags or any other kind of *tag* for that matter. Other sections of the EPC Tag Data Standard specify how EPC URIs are encoded into binary data for storage on a GS1 Gen 2 RFID Tag.

 1004
 1005
 1006
 1007
 1008
 1009

Not every GS1 Identification Key corresponds to an EPC URI, nor vice versa. For example:

A Global Trade Item Number (GTIN) by itself does not correspond to an EPC, because a GTIN identifies a *class* of trade items, not an individual trade item. The combination of a GTIN and a unique serial number, however, *does* correspond to an EPC. This combination is called a Serialized Global Trade Item Number, or SGTIN.

In the GS1 General Specifications, the Global Returnable Asset Identifier (GRAI) can be used to identify either a *class* of returnable assets, or an individual returnable asset, depending on whether the optional serial number is included. Only the form

1010 that includes a serial number, and thus identifies an individual, has a corresponding
 1011 EPC. The same is true for the Global Document Type Identifier (GDTI).
 1012 EPCs include identifiers for which there is no corresponding GS1 Identification Key;
 1013 that is, certain Class 3 identifiers as defined in Section 4.3. These include the
 1014 General Identifier, the US Department of Defense identifier, and the Aerospace and
 1015 Defence Identifier.

1016 **5. Capture – Physical Data Carriers and Data**
 1017 **Capture Infrastructure**

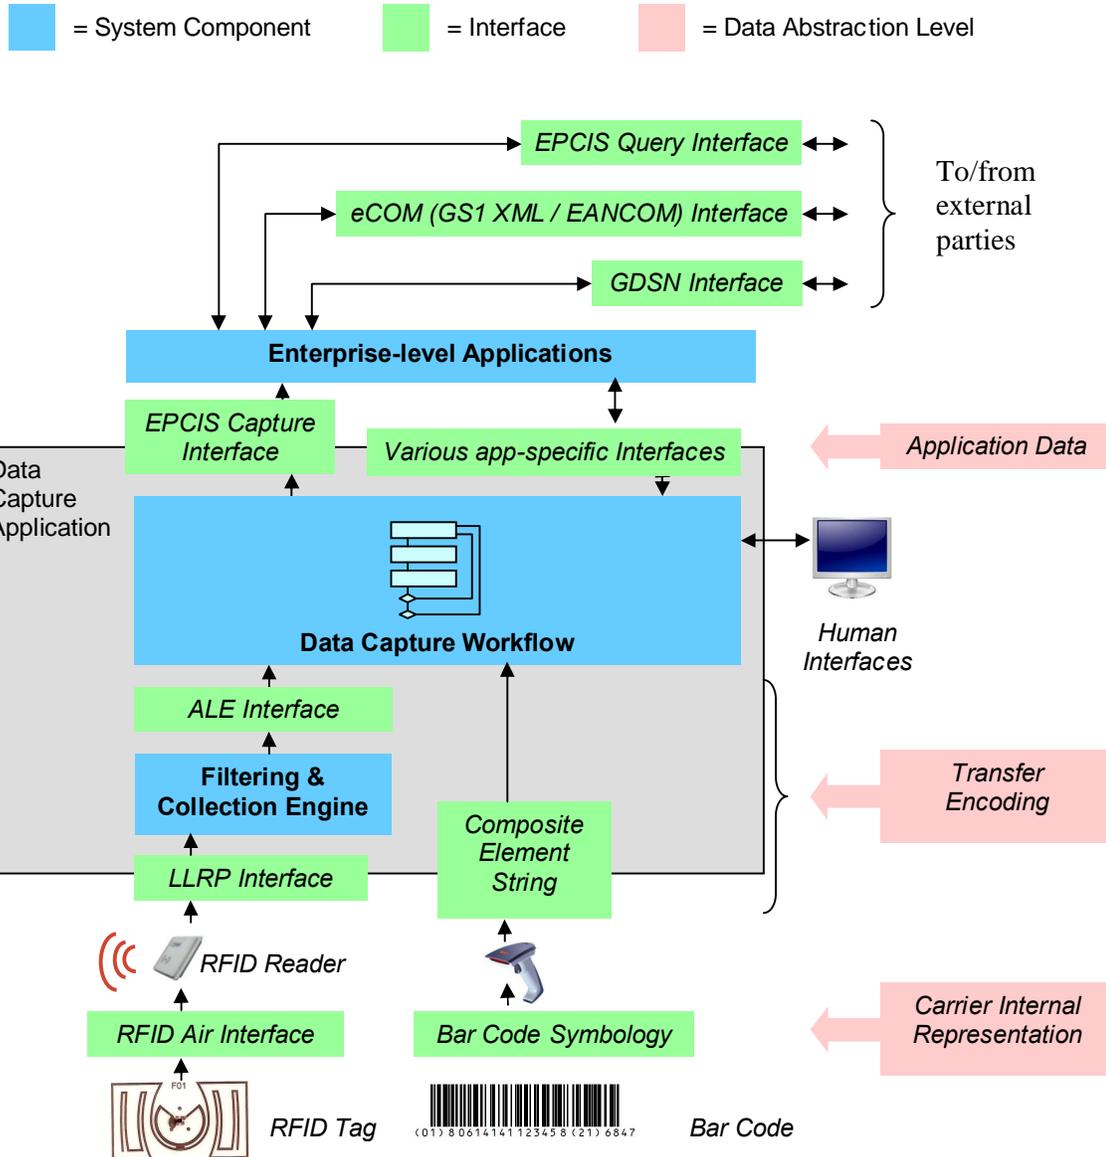

1018 The %Capture+ standards in the GS1 System are standards for automatically capturing
 1019 identifying information and possibly other data that is associated with a physical object. The
 1020 industry term Automatic Identification and Data Capture (AIDC) is sometimes used to refer to
 1021 the standards in this group, though in the GS1 System Architecture a clear distinction is
 1022 maintained between identification and data capture. A physical data carrier is a means of
 1023 physically affixing data to a physical object so that the data can be captured without human
 1024 data entry. Data carriers range in capability, from the simplest bar codes whose only
 1025 function is to deliver a single unchanging piece of data when read, to the most sophisticated
 1026 RFID tags which are small computing devices. Interaction with the latter may be more than
 1027 mere %data capture,+ though the term %capturing+ is still used as a general label for that
 1028 process. The processes involved in putting data into physical data carriers, including printing
 1029 of bar codes and programming of RFID tags, are also included under the label of %capturing.+
 1030 This section outlines the general foundations of GS1 Standards for data capture.

1031 **5.1. Data Capture Architecture**

1032 At its most fundamental, physical data capture may be used in any situation that calls for
 1033 input of data associated with a physical object. A recurring architectural pattern is that
 1034 physical data capture takes place within the context of a data capture workflow, which is a
 1035 small business process involving the handling of physical goods. Examples of data capture
 1036 workflows include: checking out trade items at point-of-sale, receiving logistics units into
 1037 inventory, marking products with unique serial numbers (here the data captured is the
 1038 association of the serialized identifier to the physical object), inventory counting of fixed
 1039 assets, and so forth. Data capture workflows mostly take place at the %edge+of a business .
 1040 in physical plant such as factories, warehouses, retail stores, as opposed to business
 1041 workflows that exist virtually within applications running in data centres.

1042 Within a given data capture workflow there may be many individual interactions with physical
 1043 data carriers. A data capture workflow may also involve interaction with humans, as well as
 1044 %back end+ information systems such as Enterprise Resource Planning (ERP), Warehouse
 1045 Management System (WMS), etc. All these things combine to create a business context
 1046 within which the data capture workflow takes place, and this gives meaning to the act of
 1047 capturing the data from the data carrier. For example, at a point of sale terminal, the
 1048 business context is usually such that scanning a bar code containing a GTIN means that one
 1049 instance of a product whose class is identified by the GTIN has just been purchased by the
 1050 customer engaged in the checkout process. However, if the POS operator presses a
 1051 different button, scanning the same bar code may instead mean that the product is being
 1052 returned rather than purchased, or that a prior checkout is being voided. In each case, the
 1053 operator of the POS terminal establishes the business context that gives meaning to each
 1054 bar code scan.

1055 This leads to a typical architecture for a data capture application. The figure below shows
 1056 the ingredients found in data capture application architecture. The exact architecture for any
 1057 given data capture application will vary from case to case . for example, not all data capture
 1058 applications use both bar codes and RFID, some data capture applications print bar codes
 1059 rather than scanning them, etc . but the diagram shows the commonly occurring
 1060 relationships between components and how GS1 Standard interfaces fit in.

 1076
 1077
 1078
 1079

At the centre of a data capture application is the data capture workflow that supervises the business process step within which data capture takes place. This is typically custom logic that is specific to the application. Beneath the data capture workflow in the diagram is the data path between the workflow and GS1 data carriers: bar codes and RFID. The green bars in the diagram denote GS1 Standards that may be used to interface to the data carriers. At the top of the diagram are the interfaces between the data capture workflow and larger-scale enterprise applications. Many of these interfaces are application- or enterprise-specific, though using GS1 data as building blocks. The Electronic Product Code Information Services (EPCIS) interface is an example of GS1 Standard that is often used as an interface between a data capture workflow and enterprise-level applications. Note that the interfaces at the top of the diagram, including EPCIS, are independent of the data carrier used at the bottom of the diagram.

The purpose of the interfaces and the reason for a multi-layer data capture architecture is to provide isolation between different levels of abstraction. Viewed from the perspective of an enterprise application (i.e., from the uppermost blue box in the figure), the entire data capture application shields the enterprise application from the details of exactly *how* data capture takes place. Through the application-level interfaces (uppermost green bars), an enterprise application interacts with the data capture workflow through data that is data

1080 carrier independent and in which all of the interaction between data capture components has
 1081 been consolidated into that data. At a lower level, the data capture workflow is cognizant of
 1082 whether it is interacting with bar code scanners, RFID Interrogators, human input, etc, but
 1083 the transfer interfaces (green bars in the middle) shield the data capture workflow from low-
 1084 level hardware details of exactly how the data carriers work. The lowest level interfaces
 1085 (green bars on the bottom) embody those internal data carrier details. This leads to different
 1086 representations for GS1 standard data for each level of abstraction, as indicated by the pink
 1087 labels in the diagram. This is discussed in more detail in the following section.

1088 5.2. Varieties of Data Carriers; Data Carrier Independence of Data

1089 A principle of GS1 standards is that data elements are defined in a data carrier neutral way
 1090 so that their semantics is the same regardless of what data carrier is used to affix them to a
 1091 physical object (and also the same outside of a physical data carrier, such as in an electronic
 1092 message). However, there is a multitude of different data carriers, each optimized for a
 1093 particular set of physical and performance constraints arising in the real world. Standards for
 1094 each data carrier therefore define a carrier-specific representation of carrier-neutral data
 1095 elements, allowing those data to be encoded in a manner compatible with the physical
 1096 constraints of the carrier. For example, in a DataMatrix bar code data elements are first
 1097 arranged into a %GS1 Element String+that frames each data element with a short identifying
 1098 character sequence and separator characters, then at a lower level encodes the resulting
 1099 sequence into a pattern of dark and light squares. In a Gen 2 RFID tag, those same data
 1100 elements are separated into different memory banks, then at a lower level encoded into a
 1101 highly compacted binary form and stored into an electronic memory circuit.

1102 In considering the complete data path from data carrier through capturing application to
 1103 business data, there are three levels of abstraction through which the data passes. From
 1104 highest to lowest, they are:

1105 *Application data* These are GS1 data elements defined in a data-carrier neutral
 1106 way. A business application sees the same data regardless of which type of data
 1107 carrier is used.

1108 *Transfer encoding* This is the representation of data used in the interface between
 1109 a capturing application and the hardware device that interacts with the data carrier
 1110 (bar code scanner or RFID interrogator). The transfer encoding provides access to
 1111 control information and carrier information (discussed below), and therefore is
 1112 different for different data carrier types.

1113 *Carrier internal representation* This is the representation of data in the data carrier
 1114 itself. In a bar code, this is the pattern of light and dark bars or squares. In an RFID
 1115 tag, this is the binary data stored in the digital memory of the RFID chip.

1116 The following table lists the data representations used at the different levels, and the
 1117 corresponding GS1 Standards that govern them:

Abstraction Level	Data Representation		Corresponding GS1 Standard	
	Bar Code	RFID	Bar Code	RFID
Application data	Raw Data Values / GS1 Element Strings		GS1 General Specifications (Section 3)	
	EPC URI		EPC Tag Data Standard (Sections 6 and 7)	

Abstraction Level	Data Representation		Corresponding GS1 Standard	
	Bar Code	RFID	Bar Code	RFID
Transfer encoding	Concatenated Element String	EPC Tag URI OID/value pairs EPC binary encoding ISO/IEC 15962 binary data	GS1 General Specifications (Section 5.9)	EPC Tag Data Standard (Sections 8 . 17)
Carrier internal representation	Bar code symbology	EPC binary encoding ISO/IEC 15962 binary data	GS1 General Specifications (Section 5)	EPC Tag Data Standard (Sections 12 . 17)

1118

1119

1120

At the levels of transfer encoding and carrier internal representation, there are three types of data that may be involved:

1121

1122

Application data Data that is delivered from the Capture layer of the GS1 System Architecture to the Share layer. Application data is data carrier independent.

1123

1124

Control data Data that is carrier-specific and is used to by the Capture layer of the GS1 System Architecture to control the interaction with the data carrier.

1125

1126

1127

1128

1129

1130

1131

1132

1133

Carrier data Data that describes the data carrier itself, as opposed to the object to which the data carrier is attached. Carrier data is most often used as control data to control the interaction with the data carrier at the Capture layer of the GS1 System Architecture. For example, an EAN/UPC bar code contains only a GTIN without an AI, so the Capture layer may need to know what type of bar code was scanned in order to interpret the data correctly. In some cases, the Capture layer may integrate carrier data into the application data that is delivered to the Share layer if needed for application purposes; however, this implies that the application will be sensitive to the choice of data carrier or be restricted to use a particular type of data carrier.

1134

The following table summarizes the three types of data for different types of data carriers.

Data Type	Bar Code	RFID
Application data	GS1 Data Elements (AIs) and/or EPC URI	
Control Data	FNC1 indicator	EPC Header Attribute bits Filter value PC/XPC bits
Carrier Data	Symbology identifier	TID XTID

1135

1136

1137

To illustrate Control Data and Carrier Data, a few examples are described in more detail below:

1138

1139

1140

1141

Code 128, DataMatrix, and QR bar code symbologies support both GS1 and non-GS1 data formats. In these bar code symbologies, Function Code 1 (FNC1) is a special symbol used to indicate whether the following data is GS1-compliant or not. This is control information that the data capture layer uses to understand how to

1142 interpret the data in the bar code. (When these bar codes include FNC1, they are
 1143 called GS1-128, GS1 DataMatrix, and GS1 QR, respectively.)

1144 In RFID tags, the filter value is control information that is used to distinguish different
 1145 tag populations. For example, item-level tags may have one filter value, and pallet-
 1146 level tags may have a different filter value. If the data capture layer only wants to
 1147 read a pallet tag, it may instruct the RFID interrogator to broadcast a command to
 1148 %urn off+ tags having an item-level filter value, so that the pallet level tag may be
 1149 read without having to spend time reading the much more numerous item-level tags.
 1150 The filter value is control information used by the data capture layer to optimize
 1151 reading performance, but is not application data. In particular, the filter value cannot
 1152 be considered to be a reliable indication of packaging level from a business
 1153 perspective.

1154 Bar code scanners include in the transfer encoding a symbology identifier, which is a
 1155 3-character string that indicates what kind of bar code was read (GS1-128, GS1
 1156 DataBar, EAN/UPC, etc). This is carrier data that describes the data carrier itself.
 1157 This might be used by the data capture layer, for example, to provide feedback to the
 1158 operator about which symbol was read.

1159 In RFID tags, the Tag Identification (TID) indicates the make and model of the silicon
 1160 chip in the RFID tag. This is carrier data which the data capture layer might use in
 1161 order to know what optional features the tag supports.

1162 In RFID tags, the Extended Tag Identification (XTID) may contain a unique serial
 1163 number that is assigned by the manufacturer of the RFID tag. This is carrier data
 1164 which the data capture layer might use to determine for quality control purposes
 1165 which tag was read, in an application where the same object is tagged with several
 1166 identically-programmed tags for the sake of robustness. As an example of using
 1167 carrier data at the application level, an anti-counterfeit application might rely on the
 1168 XTID serial number to detect if an RFID tag had been %cloned+ (i.e., a second tag
 1169 programmed with a copy of data from a first tag). This example illustrates the point
 1170 that application-level use of carrier data leads to dependence of the application upon
 1171 the data carrier: because this application relies on the RFID XTID, it is only able to
 1172 function fully using RFID and not bar codes.

1173 **5.3. Translation of Data During Physical Data Capture**

1174 As noted in the previous section, different representations of GS1 data are used at different
 1175 levels of abstraction in the typical data capture architecture. This implies that there is a
 1176 process of translation that takes place as data moves up or down in the data capture
 1177 architecture (up or down as illustrated in Section 5.1). These translations are specified in the
 1178 various GS1 Standards governing the different representations that are used, as indicated in
 1179 the table in Section 5.2.

1180 For example, the following are the steps of translation as data is read from a bar code and
 1181 transferred to an application:

1182 The pattern of bars and spaces in the bar code are analyzed to determine the
 1183 symbology type, and translated according to the symbology standard for that
 1184 particular symbology type into a GS1 composite element string

1185 The GS1 composite element string is parsed according to the GS1 General
 1186 Specifications Section 5.9 into individual GS1 Element Strings. Each GS1 Element
 1187 String consists of an Application Identifier (AI) number that identifies what kind of
 1188 data element, and the data value for that data element.

1189 The GS1 Element Strings are parsed according to the GS1 General Specifications
 1190 Section 3 to yield %aw+ data element values. Alternatively, they may be translated
 1191 according to the EPC Tag Data Standard Section 7 into an EPC URI.

1192 (Note that certain GS1 bar codes can only contain a single data element; in such cases, the
 1193 data element value may be extracted without an intermediate GS1 composite element
 1194 string.)

1195 The corresponding example for RFID has the following steps:

1196 The binary data encoded into the EPC and user memory banks is read from the tag
1197 and transferred through the RFID Interrogator's LLRP interface

1198 The binary data is decoded according to the EPC Tag Data Standard. For the EPC
1199 memory bank, the binary data is decoded according to Tag Data Standard Sections
1200 14 and 15 to yield an EPC Tag URI, which encapsulates the GS1 data elements that
1201 uniquely identify the object to which the RFID tag is affixed, along with RFID control
1202 information. For the user memory bank (which contains data supplemental to
1203 identification), the binary data is decoded according to Section 17 of the Tag Data
1204 Standard to yield OID/value pairs, each giving the value of one data element.

1205 The EPC Tag URI is decoded into an EPC URI according to Tag Data Standard
1206 Section 12. Optionally, the EPC URI may be translated according to Tag Data
1207 Standard Section 7 into a GS1 Element String or into %aw+ data element values.
1208 The OID/value pairs are also translated to GS1 Element Strings or into %aw+ data
1209 element values.

1210 (Note that in a given RFID application, one of the two memory banks might not be read and
1211 decoded, depending on the application's data requirements. The user memory bank might
1212 also be read selectively.)

1213 For applications that print bar codes or encode RFID tags, the translation processes above
1214 are reversed.

1215 As the above descriptions show, at the application level either GS1 Element Strings, %aw+
1216 data element values, or EPC URIs may be used, regardless of what type of data carrier is
1217 used at the lower levels. In this way, applications always deal with data that is independent
1218 of data carrier, even though at the lower levels the data representations are tailored to the
1219 unique operational characteristics of each data carrier.

1220 5.4. Data Capture Infrastructure Standards

1221 GS1 Standards for data capture include several interface standards that are employed in the
1222 data capture layer of a complete system. These provide a consistent way for data capture
1223 applications to interface with the hardware and infrastructure software required to interact
1224 with physical data carriers. Because of the different operating model and capabilities of bar
1225 codes and RFID, there are separate standards and architecture dealing with each. This
1226 section discusses those differences, and the GS1 Standards that apply.

1227 5.4.1. Bar Code Data Capture Infrastructure Standards

1228 Bar code data capture infrastructure standards are comparatively simple because there are
1229 only two operations one can perform on a bar code:

- 1230 Read all data elements from a single bar code
- 1231 Print a bar code containing one or more data elements

1232 Therefore, the interface to bar code equipment need only support these two operations.
1233 Both of these operations deal with the entire data content of a single bar code as a whole. In
1234 the interfaces to bar code equipment, this data content is expressed as a GS1 concatenated
1235 element string with a symbology identifier, which is a string of characters having the following
1236 parts:

1237 *Symbology Identifier* A 3-character piece of control information that identifies which
1238 type of bar code symbol is involved.

1239 *Element Strings* A series of GS1 Element Strings. Each GS1 Element String
1240 consists of two to four digits that identify the data element, followed by the data
1241 content for that data element. In a concatenated element string, these are arranged
1242 in an arbitrary order, with a separator character employed to delimit GS1 Element
1243 Strings (except in the case of certain fixed-length data elements, which have no
1244 separator and are required to precede all other data elements).

1245 From a data capture applications perspective, the operation of reading a bar code is very
 1246 similar to receiving keyboard input, in that the application simply receives a string of
 1247 characters and cannot direct commands to the bar code itself (in contrast to an RFID tag,
 1248 which *can* receive commands and participate in a bi-directional protocol with the data
 1249 capture application). For this reason, there is no formal interface standard for reading bar
 1250 code data in the GS1 System. Instead, it is expected that applications will receive bar code
 1251 data in a manner similar to keyboard input (and indeed, many bar code scanners even
 1252 emulate keyboard input at the hardware level). The GS1 General Specifications specify the
 1253 syntax of the GS1 concatenated element string as defined above, and this is what is
 1254 presented to the data capture application.

1255 The operation of printing a bar code is also centred on a GS1 concatenated element string
 1256 which specifies the data content of the printed bar code. In a typical printing application,
 1257 however, there is usually much more information to be provided to the printer. This includes
 1258 information about the bar code symbol itself such as dimensions, bar spacing, colour, and so
 1259 on. There may also be human readable information printed immediately beneath the bar
 1260 code, and the bar code may be just one element in a complete page description for a label or
 1261 other printed output that contains many types of printed data. For this reason, the interface
 1262 to print a bar code is often embedded within a fully-featured page markup language. There
 1263 are no GS1 Standards that govern this kind of interface.

1264 **5.4.2. RFID Data Capture Infrastructure Standards**

1265 Radio Frequency Identification (RFID) is a method of Automatic Identification and Data
 1266 Capture in which data is carried by an electronic device called an RFID Tag, which
 1267 communicates via radio frequency (RF) signals with a reading device called an RFID
 1268 Interrogator (also called an RFID Reader, though most such devices are capable of
 1269 writing as well as reading).

1270 Data capture from RFID tags is more complex than for bar codes, owing to the more
 1271 complex capabilities possessed by RFID tags. Among the differences are:

1272 RFID Tags can be read even when there is not a direct optical line of sight from the
 1273 RFID Tag to the RFID Interrogator. Among other things, this means that it might be
 1274 more difficult for a data capture application to know exactly which RFID Tag is being
 1275 read if many are present.

1276 A single Interrogator may read many Tags simultaneously, and so the interfaces
 1277 must deal with data from more than one Tag at a time.

1278 Data on RFID Tags is organized into multiple memory banks, each of which provides
 1279 random access. Reading and writing operations therefore must specify which
 1280 memory banks and memory addresses are to be involved.

1281 The data on RFID Tags may be added to or changed at any time, so that besides
 1282 reading and writing operations there are also add, update, and delete operations.

1283 Certain types of RFID Tags may provide additional functionality besides data storage
 1284 and retrieval; for example: encryption, authentication, access control, electronic
 1285 disabling (killing), sensors, actuators, etc. The interfaces must provide the ability to
 1286 perform these operations as well.

1287 The interaction between an Interrogator and a population of RFID Tags is a
 1288 conversational protocol that offers many features through which the performance of
 1289 the Interrogator-Tag interaction may be tuned. Interfaces must provide access to
 1290 these features.

1291 An application may utilize more than one RFID Interrogator simultaneously to
 1292 interact with a given RFID Tag population, to improve reliability. Such applications
 1293 require interfaces that allow for merging of the data streams from different
 1294 Interrogators.

1295 For these reasons, the interface between a data capture application and RFID Interrogators
 1296 is quite a bit more complex than the interface to a bar code scanner. In fact, RFID systems
 1297 tend to employ an additional layer of software between the data capture application and

1298 individual RFID hardware devices so that there are actually two interfaces between a data
 1299 capture application and the RFID Interrogator with which it interacts:

1300  **The Application Level Events (ALE) Interface** ALE is a GS1 Standard interface
 1301 between a data capture application and one or more RFID Interrogators. ALE
 1302 provides data capture applications with a high-level interface in which data from
 1303 more than one RFID Interrogator may be aggregated together, in which RFID data is
 1304 fully decoded and presented in a form most usable to application logic, and in which
 1305 data is filtered to avoid multiple reads, unwanted tags, etc. ALE also allows for
 1306 multiple applications to simultaneously interact with the same RFID Interrogators.
 1307 ALE is designed to let a data capture application focus on *what* data and operations
 1308 it wants to use in interacting with RFID tags, without exposing the details of *how* this
 1309 is accomplished in the interaction between Interrogator and Tag.

1310  **The Low Level Reader Protocol (LLRP) Interface** LLRP is a GS1 Standard interface
 1311 to a single RFID Interrogator device. It is a lower-level interface than ALE and
 1312 provides full control over the operation of the RFID Interrogator including low level
 1313 details of the Interrogator-Tag interaction. Data at the LLRP level is represented in
 1314 the same raw, encoded form that is used in the RFID Tag memory itself. LLRP
 1315 allows a single client to have full control over a single reader.

1316 When both ALE and LLRP are used together, there is typically a layer of software between
 1317 the LLRP and ALE interfaces. This software is called **filtering and collection** software.
 1318 Filtering and collection software is responsible for receiving high-level instructions from one
 1319 or more data capture applications that interface through ALE, determining how best to carry
 1320 out those instructions by commanding individual RFID Interrogator devices, and then
 1321 operating each Interrogator through LLRP. The filtering and collection software also
 1322 translates between the raw, encoded data formats used in the RFID Tag memory to the
 1323 application-friendly decoded formats used by data capture applications.

1324 Not all RFID data capture deployments use both ALE and LLRP. In some instances, a data
 1325 capture application may be written to use LLRP directly. This typically entails more work
 1326 than interfacing to ALE but in simple situations may result in less software being required. In
 1327 other instances, a proprietary interface to an RFID Interrogator is used in place of LLRP.

1328 ALE and LLRP are part of the **data path** of an RFID data capture architecture. they are
 1329 responsible for the communication of application data between RFID Tags and the
 1330 application layer. Complex RFID deployments involving many RFID Interrogators typically
 1331 also have a **control path** through which the RFID hardware devices themselves may be
 1332 configured, managed, and monitored for proper operation. This is especially necessary
 1333 when RFID devices are not directly controlled by human operators. There are two GS1
 1334 Standards that provide interfaces useful in constructing a control path for RFID
 1335 infrastructure:

1336  **The Reader Management (RM) Interface** RM is a GS1 Standard interface through
 1337 which a monitoring application may obtain information about the health and status of
 1338 an RFID Interrogator, including whether it is operational, how many tags are being
 1339 read, and so on.

1340  **The RFID Discovery, Configuration, and Initialization (DCI) Interface** DCI is a GS1
 1341 Standard interface through which an RFID Interrogator may automatically make itself
 1342 known to a network, obtain configuration information, and initialize itself so that it
 1343 communicates with filtering and collection or application software.

1344 As the ALE, LLRP, RM, and DCI standards define interfaces through which system
 1345 components communicate over a network, they are specified in layers as described in
 1346 Section 6.5.

1347 **6. Share – Business Data and Communication**

1348 This section discusses the general architectural foundations underlying GS1 Standards for
 1349 business data sharing, which complement the GS1 Standards for identification and the GS1
 1350 Standards for data capture discussed in earlier sections.

1351 All GS1 Standards are connected with business data in some way. Most business data is
 1352 concerned with real-world business entities such as trade items, legal entities, locations, and
 1353 so forth. The GS1 Standards for identification, as discussed in Section 4, provide the
 1354 essential foundation upon which it is possible to construct business data that refers
 1355 unambiguously to real-world entities. GS1 Standards for identification are therefore used in
 1356 all kinds of business data, including data for internal use and data that is shared with other
 1357 end users. To the extent that such data is generated from interactions with the physical
 1358 world the GS1 Standards for capture play a role as well.

1359 The GS1 Standards for sharing of business data discussed in this section come into play
 1360 when data is used to automate the interactions between two or more end users. In such
 1361 circumstances, the end users involved must have a common understanding of the structure
 1362 and meaning of business data, and this leads to GS1 Standards that define the **content** of
 1363 business data. Moreover, the end users must have an agreed method of communicating
 1364 data between themselves, and this leads to GS1 Standards for **communication** of business
 1365 data. Finally, the open nature of supply chains implies that an end user may not always
 1366 know in advance where to find relevant business data, and this leads to GS1 Interface
 1367 Standards for data and service **discovery** across the supply chain. In an international
 1368 environment, such standards must balance the need for the seamless flow of data across
 1369 the world with the need to respect national sovereignty and local regulation. This leads to
 1370 principles of world-wide **federation** that inform the design of GS1-provided services that aid
 1371 in discovery.

1372 These four topics are discussed in detail in the remainder of this section.

1373 6.1. Content of Standardized Business Data

1374 GS1 Standards for business data pertain to three categories of business data that are
 1375 shared between end users:

1376 **Master data** that provide descriptive attributes of real-world entities identified by
 1377 GS1 Identification Keys, including trade items, parties, and physical locations.

1378 **Transaction data** that consist of trade transactions, triggering or confirming the
 1379 execution of a function within a business process as defined by an explicit business
 1380 agreement (e.g., a supply contract) or an implicit one (e.g., customs processing),
 1381 from the start of the business process (e.g., ordering the product) to the end of it
 1382 (e.g., final settlement), also making use of GS1 Identification Keys.

1383 **Visibility event data** provide details about physical activity in the supply chain of
 1384 products and other assets, identified by keys, detailing where these objects are in
 1385 time, and why; not just within one company's four walls, but throughout the supply
 1386 chain.

1387 Transaction Data and Visibility Event Data have the characteristic that new documents of
 1388 those types are continually created as more business is transacted in a supply chain in
 1389 steady state, even if no new real-world entities are being created. Master Data, in contrast,
 1390 is more static: the Master Data for a given entity changes very slowly (if at all), and the
 1391 quantity of Master Data only increases as new entities are created, not merely because
 1392 existing entities participate in business processes. For example, as a given trade item
 1393 instance moves through the supply chain, new transaction data and visibility event data are
 1394 generated as that instance undergoes business transactions (such as purchase and sale)
 1395 and physical handling processes (packing, picking, stocking, etc). But new Master Data is
 1396 only created when a new trade item or location is added to the supply chain.

1397 These three categories of data are discussed in more detail in the following sections.

1398 6.1.1. Master Data

1399 Master Data are attributes (as defined in Section 4.1.2) of a real-world entity that are static
 1400 (unchanging through the life of the entity) or nearly so. For a trade item class, for example,
 1401 master data might include the trade item's dimensions, descriptive text, nutritional
 1402 information (in the case of a food product), and so on. The Global Product Classification

1403 (GPC) defines a code that locates a trade item within a taxonomy of all trade items; a trade
 1404 item's GPC code is therefore a very important Master Data attribute, both to describe the
 1405 trade item and to identify what sets of category-specific master data attributes might be
 1406 available for that trade item. Master Data provide the information necessary for business
 1407 applications to understand real-world entities and to process them appropriately in a given
 1408 business process.

1409 Many real-world entities occur repetitively in the business data that end users share to carry
 1410 out business. For example, the same trade item recurs in thousands or millions of purchase
 1411 orders, invoices, visibility events, and other business data as instances of that trade item are
 1412 bought and sold in the supply chain. Processing of each of these business documents may
 1413 need to refer to the attributes of the trade item involved, yet for a given trade item these
 1414 attributes are the same each time.

1415 For this reason, data sharing in the GS1 System is built on an architectural pattern in the
 1416 way that recurring business documents relate to master data:

1417 Recurring business documents including Transaction Data and Visibility Event Data
 1418 refer to real-world entities by use of a GS1 Identification Key.

1419 Master Data associates the GS1 Identification Key with the attributes that describe
 1420 the corresponding entity

1421 Applications that process recurring business documents obtain a complete set of
 1422 information by using the GS1 Identification Keys referenced in business documents
 1423 to join with the associated Master Data. In this way, the repetition of Master Data
 1424 attributes in each business document is avoided.

1425 This pattern leads to the question of how a business application obtains the Master Data it
 1426 needs to process the recurring business documents it receives. In general, for any given
 1427 real-world entity there is a well-defined producer-consumer relationship for Master Data.
 1428 The end user that creates the real-world entity is the producer of Master Data and all other
 1429 end users in the supply chain that may need to reference it are consumers. For example,
 1430 the producer of Master Data describing a trade item is the brand owner, the producer of
 1431 Master Data describing a physical location is the organization that owns or occupies the
 1432 location, and so on. The producer of Master Data for an entity is often the same end user
 1433 that creates the GS1 Identification Key that identifies the entity, or another party authorized
 1434 by the latter to do so.

1435 There are four methods envisioned in the GS1 System by which a consumer may receive
 1436 Master Data from a producer:

1437 *Synchronization In Advance* A consumer obtains Master Data prior to processing
 1438 any recurring business documents. The Master Data is often delivered in the form of
 1439 a *catalogue* that provides Master Data for a group of related real-world entities,
 1440 such as trade items belonging to a certain category or sold within a certain
 1441 geographic region. This is necessary so that all Master Data that might be needed is
 1442 available when the business documents are processed later. This is referred to as
 1443 *synchronization* because the process of obtaining Master Data in this way is
 1444 repeated periodically in order that the consumer's copy of Master Data is consistent
 1445 (*synchronized*) with the master copy published by producer.

1446 *Query On Demand* A consumer obtains Master Data for a given real-world entity
 1447 by issuing a query to a lookup service, where the query contains the GS1
 1448 Identification Key for the entity whose Master Data is desired. The query may be
 1449 issued directly to the Master Data producer (assuming the producer's identity is
 1450 known to the consumer) or to an intermediary of some kind. In this method, it is
 1451 possible to defer obtaining Master Data associated with a given GS1 Identification
 1452 Key until the consumer is processing a business document containing that particular
 1453 key.

1454 *Embedding In A Business Document* A business document itself may contain
 1455 Master Data attributes in addition to a GS1 Identification Key. The consuming
 1456 application does not need to obtain Master Data from another source.

1457
1458
1459
1460
1461

Embedding In A Physical Data Carrier A physical data carrier (bar code or RFID tag) affixed to a real-world entity may contain attributes that describe the entity. GS1 Standards for capture may be used to extract these attributes and pass them to a business application, which then does not need to obtain Master Data from another source.

1462
1463
1464

Only the first two methods in this list follow the architectural pattern described above, and so only these two methods avoid the repetition of Master Data. The last two methods are used only when it is not possible to share Master Data using one of the first two methods.

1465
1466
1467
1468
1469

In principle, Master Data may exist for any of the types of real-world entities that can be identified by GS1 Identification Keys as enumerated in the table in Section 4.2, and moreover any of the four sharing methods above may be used for any of this Master Data. In reality, GS1 Standards for Master Data are only provided for a subset of these possibilities. The table below summarizes what is currently supported:

Entity	Synchronization	Query on Demand	Embedding in Business Document	Embedding in Physical Data Carrier
Trade Item Class	Note 1	Note 3	Note 4	Note 2
Trade Item Lot			Note 4	Note 2
Trade Item Instance		Note 3	Note 4	Note 2
Logistics Unit		Note 3	Note 4	Note 2
Party	Note 1	Note 3	Note 4	
Physical Location	Note 1	Note 3	Note 4	
Returnable Asset Class		Note 3	Note 4	
Returnable Asset Instance		Note 3	Note 4	
Individual Asset		Note 3	Note 4	
Document Type		Note 3	Note 4	
Document Instance		Note 3	Note 4	
Service Relation		Note 3	Note 4	
Consignment			Note 4	
Shipment			Note 4	
Payment Slip				Note 2
Coupon		Note 3	Note 4	
Coupon Instance		Note 3	Note 4	

- 1470 Notes:
- 1471 1. The GS1 Global Data Synchronization standard provides a communication framework for
- 1472 synchronization of Master Data for trade item classes, parties, and physical locations, and
- 1473 the Catalogue Item Notification and Party Notification message standards define the Master
- 1474 Data attributes and their meanings.
- 1475 2. Many of the %supplementary data+Application Identifiers available for use in GS1 Physical
- 1476 Data Carriers provide descriptive attributes for trade item classes, trade item lots, trade item
- 1477 instances, logistics units, and payment slips. An example is Expiry, which is an attribute of a
- 1478 trade item lot or trade item instance.
- 1479 3. The EPCIS Simple Master Data Query provides a mechanism to request Master Data on-
- 1480 demand for any entity that can be identified by an Electronic Product Code (EPC) or EPC
- 1481 Pattern. However, there are not currently defined any data standards to support its use in a
- 1482 standardized way.
- 1483 4. In principle, any business document may be constructed to include Master Data. There
- 1484 are not currently any GS1 Data Standards that do this, however, because as noted above
- 1485 this practice is contrary to the architectural principles that provide for efficient sharing of
- 1486 Master Data.

1487 **6.1.2. Transaction Data**

1488  Transaction Data are business documents that are shared bilaterally between trading

1489 partners, each document serving to automate a step in a business process involving a

1490 business transaction between parties. GS1 Standards for transaction data are provided to

1491 automate business transactions commonly occurring across the entire B2B supply chain.

1492 The phrase %order to cash+is generally used to describe this scope, which includes business

1493 processes beginning with a buyer ordering goods from a supplier and progressing to the final

1494 receipt of cash by the supplier in exchange for those goods. GS1 Standards for transaction

1495 data also support other business processes, such as demand forecasting.

1496 Transaction Data are always shared within the framework of a business agreement

1497 (contract) between two parties. Each document confirms the commitment to execute the

1498 agreement; for example, sending an electronic %order+ message implies that the sender

1499 wants to receive the ordered goods according to the conditions agreed in the contract and

1500 will pay for them.

1501 The GS1 Standards for transaction data include:

- 1502 EANCOM
- 1503 GS1 XML Business Message Standards (BMS) for Plan, Order, Delivery, Pay, and
- 1504 others

1505 **6.1.3. Physical Event Data**

1506  Physical Event Data are records of the completion of business process steps in which

1507 physical entities are handled. Where Transaction Data confirms legal or financial

1508 interactions between trading partners, Physical Event Data confirms the carrying out of a

1509 physical process. Examples of physical processes that may be the subject of Physical Event

1510 Data include: affixing of identification to a newly manufactured object (%commissioning+),

1511 shipping, receiving, movement from one location to another, picking, packing, transfer at

1512 point-of-sale, and destroying.

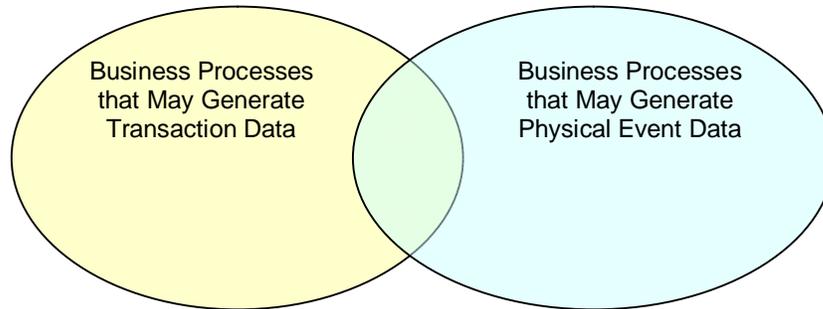

1513 Physical Event Data is complementary to Transaction Data, as some physical events occur

1514 in the absence of business transactions and conversely some business transactions take

1515 place without handling of physical objects. Where the same business process

1516 simultaneously yields Physical Event Data and Transaction Data, they provide

1517 complementary data.

1518

1519

Examples of all three possibilities:

1520

1521

1522

1523

1524

1525

1526

1527

1528

1529

In some cases, a physical event coincides with a business transaction, so that there may be a piece of Transaction Data and a piece of Physical Event Data describing different aspects of the same occurrence. For example, when goods are shipped from a loading dock, there may be a Despatch Advice (a piece of Transaction Data that confirms the sender's intent to deliver specific goods to the receiver) and a shipping EPCIS event (a piece of Physical Event Data that confirms the observation of goods leaving the loading dock). Even in such cases, the transaction data and physical event data may not be in 1:1 correspondence; for example, a single Despatch Advice may correspond to several physical events if different parts of the shipment are handled separately.

1530

1531

1532

1533

1534

A physical event may occur with no corresponding business transaction. For example, when a trade item moves from the back room+storage of a retail store to the sales area where a consumer can purchase it. This is a highly relevant event for purposes of assessing availability of product to consumers but it has no associated business transaction.

1535

1536

1537

A business transaction may take place with no corresponding physical event. For example, when a purchaser sends an order+message to a supplier, there is a legal interaction, but nothing occurring in the physical world.

1538

Each Physical Event has four data dimensions:

1539

1540

What Identification of the physical object(s) involved in the event, expressed using an identification key

1541

When The date and time when the event took place

1542

Where The physical location involved in the event, which may include:

1543

The physical location where the event took place

1544

The physical location where the objects are expected to be following the event

1545

1546

Why Details about the business process context in which the observation took place, which may include:

1547

An identification of the business process taking place at the time of the event

1548

The business state of the objects following the event

1549

1550

Links to relevant Business Transaction Data (especially in those cases where a physical event and a business transaction occur simultaneously)

1551

1552

Physical Event Data is defined by the GS1 Electronic Product Code Information Services (EPCIS) standard.

1553

6.2. Communication of Business Data

1554

1555

GS1 Standards offer several methods for communication of Business Data between end users. In summary, the methods are:

1556 “Push” methods, where one party unilaterally transfers data to another in the
 1557 absence of a prior request. Push methods may be further classified as:

1558 *Bilateral* party-to-party push, where one party transfers data directly to another
 1559 party

1560 *Publish/subscribe*, where one party transfers data to a data pool, which in turn
 1561 pushes the data to other parties who have previously expressed interest in that
 1562 data by registering a subscription (selective push)

1563 “Pull” or “query” methods, where one party makes a request for specific data to
 1564 another party, who in turn responds with the desired data

1565 It should be noted that both the pull method and the publish/subscribe method rely on
 1566 some sort of intermediate repository for data. In the case of pull methods, it is this
 1567 repository that is queried to satisfy each request. In the case of publish/subscribe methods,
 1568 the repository serves as a holding area as published data is routed to each subscriber, and
 1569 to service subscriptions which are registered after the initial publication of data. GS1
 1570 Standards, however, define only the interfaces used to transfer data; the design of
 1571 repositories that support the transfer are the responsibility of end users and solution
 1572 providers.

1573 In principle, any of the above communication methods could be used for any of the
 1574 categories of business data that are governed by GS1 business data standards. In practice,
 1575 the type of data dictates the most appropriate communication methods and GS1 Standards
 1576 support the combinations that end users have found to be most useful. They are
 1577 summarized in the table below:

Data Type	Data Standard	Available Communication Methods		
		Bi-lateral Push	Publish/Subscribe	Pull (Query)
Master Data	GDSN	✓	✓	[future]
Business Transaction Data	GS1 eCom XML EANCOM	✓		
Physical Event Data	EPCIS	✓	✓	✓

1578 In more detail:

1579 Master data

1580 The Global Data Synchronisation Network (GDSN) provides the
 1581 publish/subscribe method for transferring master data. The repository in this
 1582 case is provided by a GDSN certified data pool. The GS1 XML CIN message
 1583 format is used to transfer master data between GDSN data pools, and either this
 1584 format or the EANCOM PRICAT message format is used between an end user
 1585 and a data pool.

1586 Master data may also be pushed bi-laterally based on the use of GS1 XML CIN
 1587 or EANCOM PRICAT messages.

1588 The EPCIS Master Data Query anticipates a future ability to transfer master data
 1589 by a pull-style query. This is expected to be useful for highly granular master
 1590 data, such as very detailed physical location master data that may be important
 1591 for exception processing using detailed physical visibility data.

1592 Transaction data

1593 Bi-lateral push based on GS1 eCom XML or EANCOM is the most common
 1594 way to exchange data

1595 Visibility data

1596 EPCIS data may be transferred via a %pull+ style query using the EPCIS query
 1597 interface. In this case, a trading partner's own EPCIS database acts as the
 1598 repository to service queries, or the trading partner may outsource this to a
 1599 service provider.

1600 EPCIS data may also be transferred via a bi-lateral %push+ using EPCIS XML
 1601 (delivered via AS2).

1602 The EPCIS query interface also provides for the registration of subscriptions,
 1603 making a publish/subscribe style of data transfer possible as well.

1604 **6.3. Data and Service Discovery**

1605 GS1 Standards for business data and communication provide the means for two end users
 1606 to share business data reliably, once they have identified each other. GS1 Standards for
 1607 data and service discovery exist to help end users identify each other so that they can share
 1608 data.

1609 In general, there are three ways that one end user identifies another so that data may be
 1610 shared:

1611 *Pre-arrangement* In many cases, one end user identifies another by means of
 1612 some pre-arrangement that takes place outside the scope of any GS1 Standard, or
 1613 even outside the scope of information systems. For example, bi-lateral sharing of
 1614 business transaction data via eCom typically takes place between end users who
 1615 have identified each other in advance and agreed to trade with each other. The
 1616 establishment of the communication pathway is often a manual process. Similarly, in
 1617 the Global Data Synchronization Network for Master Data, an end user
 1618 communicates with a certified GDSN Data Pool that is identified in advance and
 1619 subscriptions to Master Data through the Data Pool are manually negotiated
 1620 between the consumer of Master Data and the producer.

1621 *Originating Party Service Lookup (ONS)* In some cases, an end user may wish to
 1622 share data with the party that originates a given real-world entity, such as the brand
 1623 owner of a trade item. Of all the supply chain participants that may have
 1624 involvement with a real-world entity, the originating party is an important special
 1625 case: it is typically the producer of Master Data associated with the entity and it also
 1626 sits at the beginning of a chain of business relationships that defines the path the
 1627 entity takes through the supply chain. The originating party also often takes
 1628 responsibility for important lifecycle events such as product recall.

1629 *Full Supply Chain Discovery (Discovery Services)* In some cases, an end user may
 1630 wish to share data with all parties that have had interaction with a given real-world
 1631 entity throughout its lifetime in the supply chain, not just the originating party. For
 1632 example, in %tracing+ goods through the supply chain it is useful to obtain
 1633 observations made by all parties that handled the goods in order to form a complete
 1634 picture of what happened.

1635 Pre-arrangement, by definition, requires no GS1 Standards to carry out. For the other two
 1636 methods, there are specific GS1 Standards and GS1 Services that support it:

1637 The GS1 Object Name Service (ONS) provides a lightweight facility for originating
 1638 party service lookup. ONS provides a means for an originating party to register one
 1639 or more service descriptors to be associated with a class-level GS1 Identification
 1640 Key (specifically, an Electronic Product Code with the serial number portion
 1641 removed). Each service descriptor specifies a type of service and an Internet
 1642 Uniform Resource Locator (URL) that can be used to reach that service. An end
 1643 user application uses the lookup protocol defined by ONS to obtain service
 1644 descriptors for a given GS1 Identification Key. The ONS standard defines the
 1645 service descriptor syntax, the available service types, and the lookup protocol.
 1646 Lookup queries themselves are directed to the ONS root server (a GS1 Service) or
 1647 to local ONS servers delegated from the root.

1648 GS1 Discovery Services is a standard currently under development, intended to
 1649 provide a means for full supply chain discovery. The standard is expected to provide
 1650 a means for any end user to register with a discovery service+ that has data
 1651 regarding a given GS1 Identification Key (e.g., EPCIS events concerned with a
 1652 specific EPC) and a means for any end user to query the discovery service to obtain
 1653 service locators so registered by other end users. The discovery service standard is
 1654 envisioned to provide a means for publishers of service locator information to restrict
 1655 who in the supply chain has access to that information, and to assist in establishing
 1656 trust when a previously unknown end user contacts another using the service locator
 1657 the latter registered with the discovery service.

1658 In principle, it is possible to share data across an entire supply chain by exploiting pre-
 1659 arrangement in a %up, 1 down+pattern. In this pattern, it is presumed that each party in a
 1660 supply chain has pre-arranged data pathways established between its immediate
 1661 predecessor (%up+) and immediate successor (%down+) with respect to the flow of goods.
 1662 Such pathways therefore form a chain along which data can be shared from any point in the
 1663 chain to any other. However, the ability to do so is limited by the willingness of all parties
 1664 along the chain to cooperate, and whether they are all operational at the time data is to be
 1665 shared.

1666 ONS and Discovery Services exist primarily to overcome the limitations of the %up, 1 down+
 1667 pattern by %short circuiting+the need to follow the entire chain. ONS is of particular interest
 1668 when the originating party is the only one with whom data needs to be shared as it allows
 1669 this party to be located without having to follow a potentially long chain of %up+relationships
 1670 to find it. Discovery Services help to avoid the ill effects of %broken chains+if one party in a
 1671 long supply chain is unwilling or unable to participate in a %up, 1 down+chain as it allows an
 1672 end user to contact all remaining parties in the supply chain directly.

1673 6.4. World Wide Federation

1674 A fundamental architecture principle of the GS1 System is that each end user retains control
 1675 over the data it originates. Each end user is responsible for its own data repositories and
 1676 need only share data when there is a business reason to do so. GS1 Standards do not
 1677 dictate the design or implementation of any data repositories, but only define the content and
 1678 meaning of data, and the interfaces through which data may be shared.

1679 There are certain types of data that are logically aggregated across many different end
 1680 users. An example is Master Data in the Global Data Synchronization Network, where each
 1681 end user would like to see a seamless resource consisting of Master Data for all trade items
 1682 identified by their Global Trade Identification Number (GTIN), regardless of the originator.
 1683 Another example is the service lookup provided by the Object Name Service, which is
 1684 conceptually a single directory of services associated with all GS1 Identification Keys.

1685 The most straightforward implementation of a global information resource of this kind is as a
 1686 single database, maintained by some central authority for the benefit of all end users and
 1687 populated by all relevant data worldwide. However, a single, centralized database has
 1688 several drawbacks:

1689 *Scalability* A single database must be large enough to accommodate the aggregate
 1690 volume of data and queries across the world. This may be quite challenging.

1691 *Local Preferences* In different countries there may be different regulatory
 1692 requirements as well as cultural preferences for critical services of this kind. In some
 1693 countries, there may be a strong preference to allow for competing services to
 1694 emerge, to help drive down costs and to avoid reliance on a single service provider.
 1695 In other countries, there may be regulations that require such services to be
 1696 operated as a governmental body. It is difficult if not impossible to accommodate all
 1697 such national preferences with a single worldwide service.

1698 *National Sovereignty* To the extent that each nation views services of this kind as
 1699 an essential part of its business infrastructure, it may be uncomfortable with any
 1700 implementation that is vulnerable in the event that some other nation withdraws its

1701 participation. A centralized service may be perceived as having this vulnerability
 1702 with respect to the nation that hosts it.

1703 For these reasons, GS1 Services intended to present an aggregated worldwide view of data
 1704 are implemented using a decentralized, federated architecture. The federated approach has
 1705 the following architectural ingredients:

1706 Data is distributed among multiple repositories, using the GS1 Identification Key as
 1707 the basis for distribution. This allows for the accommodation of local preferences in
 1708 selecting a repository for the data associated with a given key. In some localities,
 1709 this may give the end user the freedom to choose a repository service provider or
 1710 even operate its own repository service; in other localities, this may allow the
 1711 government to provide the repository service that all end users in that locality must
 1712 use.

1713 In GDSN, this is realized through the existence of multiple certified GDSN Data Pools,
 1714 each of which is the home repository for the Master Data associated with a subset of
 1715 keys.

1716 In ONS, this is realized through a hierarchical structure that allows each GS1 Company
 1717 Prefix to have a separate repository for service references.

1718 Data may be replicated among repositories so that the failure of one repository does
 1719 not affect users of others.

1720 In GDSN, this is realized through synchronization of data pools so that all data pools
 1721 receive copies of the Master Data for all keys, regardless of where the data originated.

1722 In ONS, this is realized through the ability to have multiple redundant servers at each
 1723 level of the lookup hierarchy.

1724 A directory structure is used to route a service request to the appropriate repository
 1725 service, using the GS1 Identification Key as a basis for the routing.

1726 In GDSN, the GDSN Global Registry identifies the home data pool for each GS1
 1727 Identification Key that has Master Data registered.

1728 In ONS, the root-level ONS Node routes queries to a lower-level ONS node, based on
 1729 the GS1 Company Prefix embedded in the GS1 Identification Key.

1730 A redundant mechanism may be used to avoid reliance upon a single root of the
 1731 directory structure, providing an extra degree of assurance with regard to issues of
 1732 national sovereignty. At the present time, neither GDSN or ONS have a mechanism
 1733 of this kind, however there is ongoing work to revise ONS to include one.

1734 **6.5. Layering of Interface Standards – Content vs. Syntax vs.**
 1735 **Transport**

1736 GS1 Standards that define interfaces facilitate interoperability between different system
 1737 components deployed by end users. GS1 Standards are intended to be as technology-
 1738 neutral as possible, both to give end users maximum freedom in making their own
 1739 implementation choices, as well as to ensure the longevity of GS1 Standards in the face of
 1740 rapidly changing technology. However, to actually achieve interoperability between systems
 1741 that are deployed separately, usually by different end users, it is unavoidable for GS1
 1742 Standards to specify particular choices for technology, especially as regards the technology
 1743 for communication of information between the system components interacting through an
 1744 interface.

1745 In order to reconcile these goals, GS1 Standards for interfaces are typically specified in three
 1746 layers, as follows. This includes all standards in the Share layer as well as the RFID
 1747 infrastructure standards in the Capture layer (Section 5.4.2).

1748 *Abstract Content* This is the primary layer of the interface specification. In this
 1749 layer, the roles that interact via the interface are defined, along with their specific
 1750 interactions. To the extent that messages or other data are to be exchanged
 1751 between the interacting roles, those messages or data are defined abstractly. The

1752
1753
1754
1755
1756

structure (abstract syntax) of each data structure is defined in terms of its component parts, the meanings (semantics) of these data structures are specified, and the interaction patterns (choreography) are defined. The concrete syntax is deferred to the next layer. Abstract content is often specified in GS1 Standards using the Unified Modelling Language (UML).

1757
1758
1759
1760
1761
1762
1763
1764
1765
1766

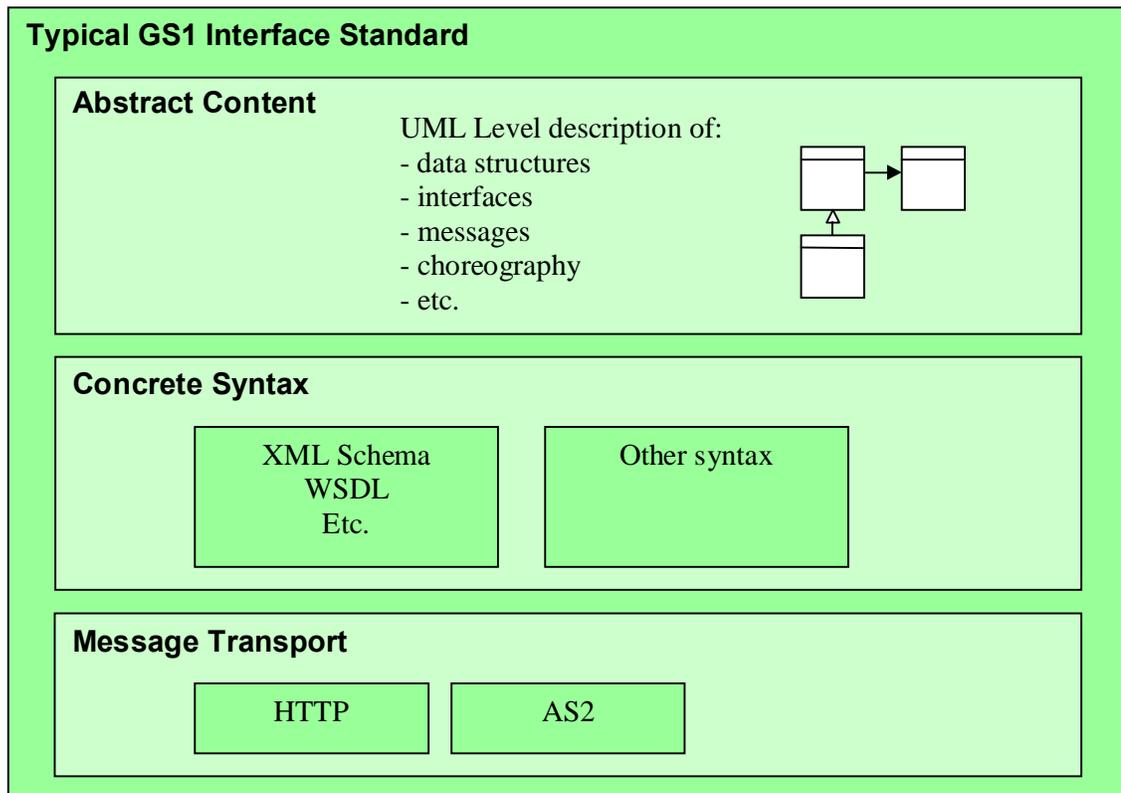

Concrete Syntax In this layer, the concrete syntax for the representation of data defined in the abstract content layer is specified. It is in this layer that schema definitions or other formal syntax descriptions are found. Many standards provide a single concrete syntax definition, but some standards may provide two or more alternative concrete syntaxes for the same abstract syntax. One concrete syntax is preferred, as having choices detracts from interoperability. Occasionally more than one syntax is necessary, however, in order to accommodate different technologies or performance goals. (An example is GS1 XML, which is a newer syntax for electronic commerce messages compared to the earlier EANCOM syntax, but both exist due to the large installed base of EANCOM.)

1767
1768
1769
1770
1771
1772
1773
1774
1775

Message Transport In this layer, the means for delivering a message having a particular syntax from one side of the interface to another is specified. Message transport tends to be the area where there is the most variety in the technical choices desired by end users, and so standards often offer a choice of different message transports that can be negotiated between the parties. The layered structure ensures, however, that regardless of the choice of message transport the content of the messages may have the same syntax, and in all cases have the same meaning. This confines the effects of technology choices to a small layer that is well separated from the content layer.

1776
1777

These layers are illustrated in the figure below (in this figure, the specific technologies mentioned are illustrative only; a given standard may specify a different set of options):

1778

1779 7. Digital Supply Chain Methodology

1780 The GS1 System provides the foundation for an approach to the integration of information
 1781 across supply chains. This approach, called the *digital supply chain*, provides for the
 1782 maximum flexibility in utilizing information to improve supply chain business processes.

1783 The digital supply chain is a natural evolution in the way supply chains operate. In the
 1784 distant past, companies interacted by delivering physical goods to each other. As the need
 1785 to have accompanying information arose, such information was delivered physically along
 1786 with the goods in the form of paper documents. Physical documentation that accompanies
 1787 physical goods has inherent limitations: the communication is one-way, the sender must
 1788 anticipate the information needs of the recipient, and the content of such information tends to
 1789 be negotiated separately with each trading partner leading to difficulties in scale in an open
 1790 supply chain. The ability to affix machine-readable information to physical objects through
 1791 bar code or RFID offers considerable benefits compared to paper information, but if it is
 1792 nothing more than a copy of the same information carried in paper documents it suffers from
 1793 the same disadvantages.

1794 The central idea of a digital supply chain is that all information exchange is carried out
 1795 electronically, through network pathways that effectively parallel the physical path taken by
 1796 goods. The physical pathway and the parallel digital pathway are illustrated at the bottom
 1797 and top, respectively, of the diagram in Section 3.1. In a fully realized digital supply chain,
 1798 physical objects carry only a globally unique identifying code (namely, a GS1 Identification
 1799 Key), and all other information is communicated digitally, using the unique identifiers to link
 1800 the information to the physical objects. This overcomes the limitations of paper document
 1801 exchange, because information may flow in both directions (and, indeed, in other directions
 1802 not corresponding to physical flow), and information may be sent in advance of physical
 1803 shipment or afterwards on demand. Changes in information needs may be accommodated
 1804 without the need to re-engineer the business processes for marking and scanning physical
 1805 objects. The role of global standards becomes paramount, so that in an open supply chain
 1806 the data is consistent regardless of which trading partner is communicating with whom; on
 1807 the other hand, the use of global standards facilitates the rapid integration of new partners
 1808 into the overall open supply chain.

1809 A critical question is at what level physical objects should be identified. For example, in
 1810 many situations it is sufficient to identify trade items at the class level, using a Global Trade
 1811 Item Number (GTIN). In other situations, it is necessary to distinguish narrower groupings,
 1812 such as trade items from a given lot or having a common expiration date. This becomes
 1813 challenging if there are several such groupings to which a single item may belong in different
 1814 business contexts. Fully serialized identification, in which each trade item or other physical
 1815 object has a globally unique identifier that is different from every other object, is the most
 1816 flexible in this regard.

1817 Different types of information lead to different approaches for information sharing. As noted
 1818 in Section 6, the GS1 System recognizes Master Data which is more static in nature and
 1819 where there is typically a one-to-many relationship between data producer and data
 1820 consumer, Transaction Data is continually created as business is carried out and typically
 1821 communicated one-to-one between direct trading partners, and Physical Event Data which is
 1822 also continually created but which may be exchanged across a supply chain and on demand.
 1823 All such data uses GS1 Identification Keys to link to the physical world.

1824 To summarize, the digital supply chain approach is as follows:

1825 *Globally Unique Identification* All assets of interest in the supply chain should be
 1826 identified with a globally unique identifier at the lowest level.

1827 *Affixing As Few Data Carriers as Possible* If an asset is physically handled, one or
 1828 more physical data carriers should be affixed to carry the asset's unique
 1829 identification (and no other information; see below). The circumstances in which the
 1830 asset is handled will dictate which data carriers are suitable (e.g., UHF RFID, GS1-
 1831 128 Bar Code, GS1 DataMatrix, etc); in general, as few data carriers as possible
 1832 should be used.

1833 *Use Master Data to Carry Asset Attributes* All descriptive attributes of an asset
 1834 should be carried in master data associated with the asset's unique identification
 1835 rather than carried on the asset itself through supplementary data in a physical data
 1836 carrier. Supply chain parties should standardize the smallest set of master data
 1837 attributes that is adequate to convey what business processes need to know about
 1838 an asset, and communicate those attributes using synchronization or other means.

1839 *Use Common Data Definitions in Business Documents, Internal and External*
 1840 Business data exchanged between applications within a company and between
 1841 companies should refer to assets using their unique identification. Descriptive
 1842 information about those assets needed to process the data may then be obtained
 1843 through master data. To the extent possible, other data contained in electronic
 1844 documents should make use of standardized definitions.

1845 This approach is directly supported by GS1 Standards for Identification, Capture, and
 1846 Sharing.

1847 8. Glossary

Term	Sections	Definition
Abstract Content (standards layer)	6.5	The layer of an Interface Standard that specifies the interactions that occur over the interface, including the abstract structure, meaning, and interaction patterns, but not including concrete syntax or transport
AIDC	2.3, 5	See <i>Automatic Identification and Data Capture</i>
ALE	5.4	See <i>Application Level Events</i>
Application Data (in physical data carriers)	5.2	Business data that are carried in Physical Data Carriers, defined in a data carrier-neutral way
Application Level Events (ALE)	5.4	A GS1 Standard interface between a Data Capture Application and one or more Radio-Frequency Identification (RFID) Interrogators (readers)
Application Standard	3.1	A type of GS1 Standard that specifies a particular set of technical standards to which end user systems must conform in a particular business application
Assign	2.4	A function of GS1 Services: to assign identification codes according to GS1 Standards for identification
Attribute (data modelling)	4.1	A piece of information associated with an Entity. An attribute may be recognized if one can construct a sentence of the following form: "The [attribute name] of [entity] is [attribute value]."
Automatic Identification and Data Capture (AIDC)	2.3, 5	The reading and writing of information from Physical Data Carriers, in particular, bar codes and radio-frequency identification (RFID) tags

Term	Sections	Definition
Capture	2.3, 5	A category of GS1 Standards, encompassing the standards that are used to capture data that is carried directly on physical objects, bridging the world of physical things and the world of electronic information
Carrier Data (in Physical Data Carriers)	5.2	Data contained in a Physical Data Carrier that describes the data carrier itself, as opposed to the object to which the data carrier is affixed
Carrier internal representation	5.2	The representation of data as it exists within a Physical Data Carrier. In a bar code, this is the pattern of light and dark bars or squares. In a Radio-Frequency Identification (RFID) tag, this is the binary data stored in the digital memory of the RFID chip
Class 1 Key	4.3	GS1 Identification Keys administered by GS1 and fully under its control
Class 2 Key	4.3	GS1 Identification Keys administered by allocating a portion of GS1 numbering capacity to an external agency
Class 3 Key	4.3	An identification key that is administered and controlled outside GS1 but which is supported in some part of the GS1 System. A Class 3 key is not a %GS1 Identification Keys+
Class 4 Key	4.3	An identification key that is administered and controlled outside GS1 and not supported in any part of the GS1 System. A Class 4 key is not a %GS1 Identification Keys+
Closed Supply Chain	2.2	A Supply Chain consisting of a fixed universe of trading partners, all of whom are known in advance
Compound Key (data modelling)	4.1	Two or more Attributes which together serve as a Key, where no subset of those attributes taken by themselves would do so
Concrete Syntax (standards layer)	6.5	The layer of an Interface Standard which specifies a specific syntax that realizes the abstract data structures defined in the Abstract Content layer
Control Data (in physical data carriers)	5.2	Data contained in a Physical Data Carrier that is used to by the Data Capture Application to control the interaction with the data carrier
Data Capture Application	4.5	Software responsible for interacting directly with AIDC Data Carriers, and coordinating this interaction with the enclosing business process
Data Carrier	2.3, 5	See <i>Physical Data Carrier</i>
Data Standard	3.1	A type of GS1 Standard that defines the syntax and semantics of data

Term	Sections	Definition
DCI	5.4	See <i>RFID Discovery, Configuration, and Initialization Interface</i>
Discover	2.4	A function of GS1 Services: to provide for one party to discover the existence of identification keys registered by others and the data associated with those keys, including associated services
Discovery Services	6.3	A GS1 Standard currently under development, intended to provide a means for a supply chain party to locate all sources of data within the supply chain that meet specified criteria
Electronic Product Code Uniform Resource Identifier (EPC URI)	4.4	A uniform syntax for Class 1, Class 2, and Class 3 Keys that identify specific physical objects, based on Internet Uniform Resource Identifier (URI) syntax
Element String	4.4, 5.4	See <i>GS1 Element String</i>
End User	1	An organization that employs the GS1 System as a part of its business operations
Entity (data modelling)	4.1	Something in the real world that is the subject of information in an information system
EPC URI	4.4	See <i>Electronic Product Code Uniform Resource Identifier</i>
Foreign Key (data modelling)	4.1	A key-valued Attribute; i.e., an Attribute of an Entity whose value is conceptually another Entity, represented in an information system as the Key value for the referenced Entity
GDD	3.4	See <i>Global Data Dictionary</i>
Global Data Dictionary (GDD)	3.4	A compendium of the data elements defined across all GS1 Standards. The GDD is not itself a GS1 Standard, but rather is a tool which helps to ensure consistency across all GS1 Standards
Global Standards Management Process (GSMP)	1, 3.1	The process by which GS1 End Users and Solution Providers collaborate to create GS1 Standards and GS1 Guidelines, with facilitation by GS1
GS1 Element String	4.4, 5.4	A syntax for representing a collection of data elements, including GS1 Identification Keys and Supplementary Data, that is used in bar codes
GS1 Guideline	3.1	A document that provides information considered useful in implementing one or more GS1 Standards
GS1 Identification Key	4.1, 4.2	An identifier defined by GS1 Standards that is usable as a Key to refer to a specific business Entity

Term	Sections	Definition
GS1 Network Service	1, 2.4, 3.1	A GS1 Service that is delivered to End Users as an information service via the global Internet
GS1 Service	1, 2.4, 3.1	A facility offered or coordinated by the GS1 Global Office (GO) that provides benefit or assistance to other parties
GS1 Solution	3.1	A set of elements from the GS1 portfolio, those elements being GS1 Standards, GS1 Guidelines, GS1 Services, and other GS1 Solutions, brought together to address a specific business need or purpose
GS1 Standard	2.3, 3.1	A specification that defines the behaviour of one or more system components so that certain goals are achieved
GS1 System	1	The sum total of all the artefacts created by the GS1 community through GS1 community development processes, including GS1 Standards, GS1 Guidelines, GS1 Solutions, and GS1 Services
GS1 System Landscape	1	A companion document to the GS1 System Architecture, which provides a structured, complete catalogue of all GS1 Standards
GSMP	1, 3.1	See <i>Global Standards Management Process</i>
Identify	2.3, 4	A category of GS1 Standard, encompassing the standards that define unique identification codes which may be used by an information system to refer unambiguously to a real-world entity
Interface Standard	3.1	A type of GS1 standard that defines an interaction between system components, often by defining the syntax and semantics of messages that are exchanged between system components
Key (data modelling)	4.1	An Attribute or group of Attributes of an Entity that serves to uniquely identify that Entity, within some specified domain
LLRP	5.4	See <i>Low-Level Reader Protocol</i>
Low-Level Reader Protocol	5.4	A GS1 Standard interface to a single Radio-Frequency Identification (RFID) device
Master Data	6.1	Attributes of a real-world Entity that are static (unchanging through the life of the entity) or nearly so
Message Transport (standards layer)	6.5	The layer of an Interface Standard that specifies the means for delivering a message from one side of the interface to the other

Term	Sections	Definition
Object Name Service	6.3	A GS1 Service, whose interface is governed by a corresponding GS1 Standard, that provides a lightweight facility to identify services associated with a GS1 Identification Key that are registered by the party that originated the key
ONS	6.3	See <i>Object Name Service</i>
Open Supply Chain	2.2	A Supply Chain in which the complete set of trading partners is not known in advance and which changes continually.
Physical Data Carrier	2.3, 5	Generic term for a Bar Code or RFID Tag; a means of physically affixing machine-readable data to a physical object
Physical Event Data	6.1	Records of the completion of business process steps in which physical entities are handled
Primary Key (data modelling)	4.1	An Attribute (or Attributes) that is used consistently by an application as the Key to refer to an Entity within a specified domain
Profile	3.1	A type of standard whose normative content consists exclusively of references to other standards along with normative constraints upon their use
Reader Management	5.4	A GS1 Standard interface through which a monitoring application may obtain information about the health and status of a Radio-Frequency Identification (RFID) Interrogator (reader)
Register	2.4	A function of GS1 Services: to register identification keys and associated data
RFID Discovery, Configuration, and Initialization Interface	5.4	A GS1 Standard interface through which an Radio-Frequency Identification (RFID) Interrogator (reader) may automatically make itself known to a network, obtain configuration information, and initialize itself so that it communicates with filtering and collection or application software
RM	5.4	See <i>Reader Management</i>
Share	2.3, 6	A category of GS1 Standards, encompassing the standards that facilitate the sharing of data between business applications and trading partners
Simple Key (data modelling)	4.1	A single Attribute that serves as a Key
Solution Provider	1	An organization that implements for End Users systems that are based upon or implement the GS1 System

Term	Sections	Definition
Supplementary Data	4.2	Attributes of Entities, other than Keys, defined by GS1 Standards, that may be directly affixed to an Entity using a GS1 Data Carrier
Supply Chain	2.2	A set of companies or other organizations involved in trading and other business relationships with one another
Symbology Identifier	5.4	A 3-character piece of Control Information used in bar code interface standards to identify which type of bar code symbol is read
Technical Standard	3.1	A type of GS1 Standard that defines a particular set of behaviours for a system component. Technical Standards include Data Standards and Interface Standards
Transaction Data	6.1	Business documents that are shared bilaterally between trading partners, each document serving to automate a step in a business process involving a business transaction between parties
Transfer Encoding	5.2	The representation of data used in the interface between a Data Capture Application and the hardware device that interacts with the Data Carrier (bar code scanner or Radio-Frequency Identification (RFID) Interrogator)
